

ON THE THIN BOUNDARY OF THE FAT ATTRACTOR

ARTUR O. LOPES AND ELISMAR R. OLIVEIRA

ABSTRACT. For, $0 < \lambda < 1$, consider the transformation $T(x) = dx \pmod{1}$ on the circle S^1 , a C^1 function $A : S^1 \rightarrow \mathbb{R}$, and, the map $F(x, s) = (T(x), \lambda s + A(x))$, $(x, s) \in S^1 \times \mathbb{R}$. We denote $\mathcal{B} = \mathcal{B}_\lambda$ the upper boundary of the attractor (known as fat attractor). We are interested in the regularity of \mathcal{B}_λ , and, also in what happens in the limit when $\lambda \rightarrow 1$. We also address the analysis of following conjecture which were proposed by R. Bamón, J. Kiwi, J. Rivera-Letelier and R. Urzúa: for any fixed λ , generically C^1 on the potential A , the upper boundary \mathcal{B}_λ is formed by a finite number of pieces of smooth unstable manifolds of periodic orbits for F . We show the proof of the conjecture for the class of C^2 potentials $A(x)$ satisfying the twist condition. We do not need the generic hypothesis. When λ is close to 1 and the potential A is generic a more precise description can be done. In this case the pieces of C^1 curves on the boundary have some special properties. Finally, we present the general analysis of the case where A is Lipschitz and its relation with Ergodic Transport.

1. INTRODUCTION

Consider, $0 < \lambda < 1$, the transformation $T(x) = dx \pmod{1}$, where $d \in \mathbb{N}$, a Lipschitz function $A : S^1 \rightarrow \mathbb{R}$, and, the map

$$(1) \quad F(x, s) = (T(x), \lambda s + A(x)), \quad (x, s) \in S^1 \times \mathbb{R}.$$

Note that $F^n(x, s) = (T^n(x), \lambda^n s + [\lambda^{n-1}A(x) + \lambda^{n-2}A(T(x)) + \dots + \lambda A(T^{n-2}(x)) + A(T^{n-1}(x))])$. Here we use sometimes the natural identification of S^1 with the interval $[0, 1)$. We will assume that A is at least Lipschitz. In this case results obtained under such hypothesis could also apply to the shift case (in this setting the potential A is defined in the Bernoulli space), that is, for σ instead of T . For certain results in the paper we assume that $A : S^1 \rightarrow \mathbb{R}$ is of class C^1 or sometimes C^2 .

The structure of the paper is the following: some results are of general nature and related just to the concept of λ -calibrated subaction (to be defined later). In this case you need just to assume that A is Lipschitz (see section 9).

Other results are related to the dynamics of F and to the conjecture presented in [7]. In this case we assume that the potential A satisfies some differentiability assumptions and also the twist condition (to be defined later). The analysis of the regularity of the boundary of the attractor requires the understanding of λ -calibrated subactions. The twist condition assures some kind of transversality condition as we will see.

Note that for x fixed the transformation $F(x, \cdot)$ is bijective over the fiber over $T(x)$. As an illustration we point out that in the case $d = 2$, given (x, z) , with $x \in S^1$ and $z \in \mathbb{R}$, consider x_1 and x_2 the two preimages of x by T . Then, $F\left(x_1, \frac{z - A(x_1)}{\lambda}\right) = (x, z) = F\left(x_2, \frac{z - A(x_2)}{\lambda}\right)$.

It is known that the non-wandering set Ω_λ of $F = F_\lambda$ is a global attractor of the dynamics of F : the forward orbit of every point in $S^1 \times \mathbb{R}$ converges to Ω_λ and F is transitive on Ω_λ . In fact, F is topologically semi-conjugate to a solenoidal map on Ω_λ (see Section 2 in [7]).

In Figure 1 we show the points of the attractor in the case of $T(x) = 2x \pmod{1}$, $\lambda = 0.51$ and $A(x) = \sin(2\pi x)$ (see page 1013 in [36]). In this case the boundary of the attractor is a finite union of smooth curves.

According to [7] Ω_λ is the set of all (x, s) with a bounded infinite backward orbit (i.e., there exists $C > 0$ and (x_n, s_n) , $n \in \mathbb{N}$, such that, $F^n(x_n, s_n) = (x, s)$ and $|s_n| < C$, for all, $n \in \mathbb{N}$).

This transformation F is not bijective. Anyway, the fiber over x goes in the fiber over $T(x)$. If $s_1 < s_2$ is such that (x, s_1) and (x, s_2) are in the attractor, then (x, s) is in the attractor for any $s_1 < s < s_2$ (see section 2.2 in [7]). Note that the iteration of F preserves order on the fiber, that is, given x , if $t > s$, then $\lambda s + A(x) < \lambda t + A(x)$.

We denote $\mathcal{B} = \mathcal{B}_\lambda$ the upper boundary of the attractor. We are interested in the regularity of \mathcal{B}_λ and also in what happens with this boundary in the limit when $\lambda \rightarrow 1$. The upper boundary is invariant by the action of F . The analysis of the lower boundary is similar to the case of the upper boundary and will not be considered here.

The study of the dimension of the boundary of strange attractors is a topic of great relevance in non-linear physics [33] and [19]. The papers [20], [1] and [21] discuss somehow related questions. We want to analyze a case where this boundary may not be a union of piecewise smooth curves.

In Figure 2 we show the image of the fat attractor for the case of $A(x) = -(x - 0.5)^2$, $\lambda = 0.51$, and $d = 2$. In this case the boundary is the union of two piecewise smooth curves as we will see.

We present in the end of the paper several pictures obtained from computer simulations which illustrate the mathematical results that we present here (see section 8).

We believe that the terminology fat attractor used by M. Tsujii is due to the fact that when $d = 2$, $0.5 < \lambda \leq 0.51$, and $A(x) = \sin(2\pi x)$, then, F is such that there exist a SBR probability which is absolutely continuous with respect to the Lebesgue measure on $S^1 \times \mathbb{R}$ (see Example 1 and Figure 1 in [36]).

It is known that \mathcal{B}_λ is the graph of a Lipschitz function $b_\lambda : S^1 \rightarrow \mathbb{R}$ (see [36] and [7]) if A is Lipschitz. We will give a proof of this fact later. b_λ will be called the λ -calibrated subaction.

One of our main motivations for the present work is the following conjecture (see [7]): for any fixed λ , generically C^1 on the potential A , the upper boundary \mathcal{B}_λ is formed by a finite number of pieces of unstable manifolds of periodic orbits of F .

We do not need here the generic hypothesis but we will require the twist condition to be defined later. However, for a generic potential A more things can be said.

The twist hypothesis is natural in problems on Optimization (see [8]) and in problems on Game Theory (see [35]). The twist property for a potential A is presented in Definition 10 in Section 3.

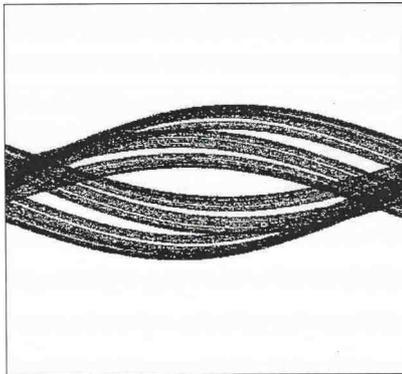

FIGURE 1. The fat attractor for the case of $A(x) = \sin(2\pi x)$, $\lambda = 0.51$, and $d = 2$. The picture indicates that the upper boundary is piecewise smooth. It is the envelope of several smooth but non periodic curves.

In the same spirit of [30] the idea here is to use an auxiliary family of functions $W_w(x) = W(x, w)$ indexed by $w \in \{1, 2, \dots, d\}^{\mathbb{N}}$ such that for each w we have $W_w : (0, 1) \rightarrow \mathbb{R}$ is, at least C^1 (it is C^2 in the case we consider). This function W of the variable (x, w) is called involution kernel. W_w is not necessarily periodic on S^1 (see pictures on section 8 where a certain S replaces the above W). A natural strategy would be to assume that A satisfies a twist condition and to show that there exists a finite number of points w_j , $j = 1, 2, \dots, k$, and a corresponding set of real values $\alpha_1, \alpha_2, \dots, \alpha_k$, such that, for each $x \in S^1$ we have

$$(2) \quad b_\lambda(x) = \max_{j=1,2,\dots,k} \{\alpha_j + W(x, w_j)\},$$

where the graph of b_λ is \mathcal{B}_λ .

In [29] the results assume, among other things, that an special point (the turning point) was eventually periodic. Here we will just use the fact that A satisfies a twist condition. We will show that the conjecture is true when A satisfies a twist condition (see Corollary 15 and comments after Corollary 15 on section 4). We point out that the twist condition is an open property in the C^2 topology. The main problem we analyze here could also be expressed in the C^2 topology.

Expressions of the kind (2) appear in Ergodic Transport (see [29] [30] [28] [32]). Equation (11) just after Theorem 44 describes relation (2) under certain general hypothesis: the Lipschitz setting (see section 9).

We apply all the previous results to the case when A is quadratic in section 7. The main problem we analyze here could also be expressed in the C^2 topology.

In section 9 we describe some general properties related to Ergodic Transport for the setting we consider here.

2. λ -CALIBRATED SUBACTIONS AND λ -MAXIMIZING PROBABILITIES

Definition 1. *Given a continuous function $: S^1 \rightarrow \mathbb{R}$ and $\lambda \in (0, 1)$, we say that a continuous function b_λ is a λ -calibrated subaction for A , if for all $x \in S^1$, $b(x) = \max_{T(y)=x} \{\lambda b(y) + A(y)\}$.*

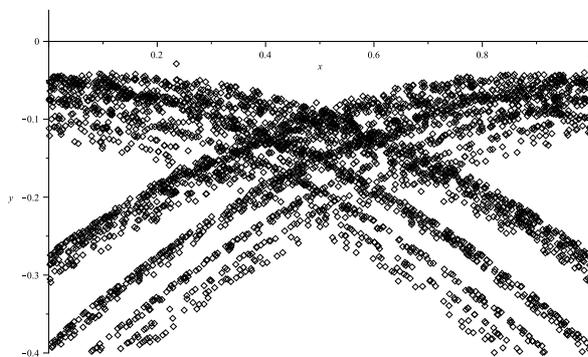

FIGURE 2. The fat attractor for the case of $A(x) = -(x - 0.5)^2$, $\lambda = 0.51$, and $d = 2$. The picture indicates that the upper boundary is piecewise smooth. It is the envelop of two smooth but non periodic curves.

A similar concept can be consider when the dynamics is defined by the shift and not T (see section 9).

When A is Lipschitz for each $\lambda \in (0, 1)$ the function b_λ above exist, is Lipschitz and it is unique (see [10]). The existence of such b_λ when A is Lipschitz is also presented in the survey paper [27].

About the interest in such family b_λ we can say that in Aubry-Mather theory and also in Optimization a similar kind of problem is considered in problems related to the so called infinite horizon discounted Hamilton-Jacobi equation. It provides an alternative method for showing the existence of viscosity solutions (see [22], [18] and [17]). Thanks to the formal association with Optimization and Economics the analysis of such family b_λ , which takes in account values $\lambda \in (0, 1)$, can be called the discounted problem for the potential A . If A is Lipschitz it is known (see [7]) that the upper boundary of the attractor is the graph of the Lipschitz λ -calibrated subaction $b_\lambda : S^1 \rightarrow \mathbb{R}$.

The above result means that if the point $(x, b_\lambda(x))$ is in the upper boundary of the attractor, then, there is a point y such that $T(y) = x$, and $F(y, b_\lambda(y)) = (x, b_\lambda(x))$. In this way the analysis of the dynamics of F on the boundary of the attractor is quite related to the understanding of λ -calibrated subactions.

Note that if b is the λ -calibrated subaction for A , then, $b + \frac{g}{\lambda}$ is the λ -calibrated subaction for $A + \frac{g \circ T}{\lambda} - g$. In order to obtain our main result on the boundary of the attractor we have to investigate properties of λ -calibrated subactions. The three keys elements on our reasoning are: probabilities with support in periodic orbits (see section 2), a relation of the kind (2) for the function b whose graph is the boundary of the attractor (see section 3) and the twist condition (see section 4).

We will present now some general results on λ -calibrated subactions. We denote by τ_i , $i = 1, 2, \dots, d$, the inverse branches of T . For each i the transformation τ_i has domain $[i - 1/d, i/d]$. Given x , if i_0 is such that $b(x) = \lambda b(\tau_{i_0}(x)) + A(\tau_{i_0}(x))$, we say $\tau_{i_0}(x)$ realizes $b(x)$ (or, realizes x). We can also say that i_0 is a symbol which realizes $b(x)$. One can show that for $d = 2$, for any Holder A , there exist x such that $b(x)$ has two different $\tau_{i_0}(x)$ realizers. In this way realizers are not always unique. For fixed $x_0 \in S^1$ consider x_1 such that $b(x_0) = \lambda b(x_1) + A(x_1)$, and $T(x_1) = x_0$. Then, there exist a realizer i_0 such that $\tau_{i_0}(x_0) = x_1$. Now take x_2 such that $b(x_1) = \lambda b(x_2) + A(x_2)$ and $T(x_2) = x_1$. In the same way as before, there exist i_1 such that $\tau_{i_1}(x_1) = x_2$. In this way get by induction a sequence $x_k \in S^1$ such that $T(x_k) = x_{k-1}$. This also defines an element $a = a(x_0) = (i_0, i_1, \dots, i_n, \dots) \in \Sigma = \{1, \dots, d\}^{\mathbb{N}}$, where $\tau_{i_k}(x_k) = x_{k+1}$. This a depends of the choice of realizers we choose in the sequence of preimages. We say $(x_0, a(x_0)) \in S^1 \times \{1, 2, \dots, d\}^{\mathbb{N}}$ is an optimal pair. Note that for each $x_0 \in S^1$ there exist at least one optimal pair. For each x_0 we consider a fixed choice $a(x_0)$, and, the corresponding sequence $x_k \in S^1$, $k \in \mathbb{N}$.

Consider the probability $\mu_n = \sum_{j=0}^{n-1} \frac{1}{n} \delta_{x_j}$ and μ_λ any weak limit of a convergent subsequence μ_{n_k} , $k \rightarrow \infty$. The probability μ_λ on S^1 is T invariant and satisfies

$$\int (b(T(x)) - \lambda b(x) - A(x)) d\mu_\lambda = 0.$$

Note that $b(T(z)) - \lambda b(z) - A(z) \geq 0$ for all $z \in S^1$. In this way **for z in the support of μ_λ** we get the **λ -cohomological** equation

$$(3) \quad b(T(z)) - \lambda b(z) - A(z) = 0.$$

Therefore, μ_λ is maximizing for the potential $A(z) - b(T(z)) + \lambda b(z)$. For z in the support of μ_λ we have that $F(z, b(z)) = (T(z), b(T(z)))$.

Moreover, in this case

$$(4) \quad b(T(z)) = \max_{T(y)=T(z)} \{\lambda b(y) + A(y)\} = \lambda b(z) + A(z).$$

Definition 2. Any probability which maximizes $A(z) - b(T(z)) + \lambda b(z)$ among T -invariant probabilities, where b is the λ -calibrated subaction, will be called a λ -maximizing probability for A .

Any μ_λ obtained from a point x_0 and a family of realizers described by a certain $a = a(x_0)$ as above is a λ -maximizing probability for A . Note that μ_λ is not maximizing for A but for the potential $A(z) - b(T(z)) + \lambda b(z)$. General references for maximizing probabilities are [6], [9], [11], [16], [23], [26], and [27]. As we are maximizing among invariant probabilities we can also say that μ_λ is maximizing for the potential

$$A(z) + (\lambda - 1)b(z) = A(z) - b(T(z)) + \lambda b(z) + [b(T(z)) - b(z)].$$

Proposition 3. If z is a point in a periodic orbit of period k and moreover z is in the support of the maximizing probability μ_λ , then the realizer a can be taken as a periodic orbit of period k for the shift σ acting in the Bernoulli space. We call such probability invariant for the shift of dual periodic probability.

Proof. In order to simplify the reasoning suppose $k = 2$. Note that $T(z)$ is also in the support of the maximizing probability μ_λ . In this case, from (3) we have that $b(T(T(z))) = \lambda b(T(z)) + A(T(z))$ because $T(z)$ is in the support of μ_λ . From equation (4)

$$b(z) = b(T(T(z))) = \max_{T(y)=T^2(z)=z} \{\lambda b(y) + A(y)\} = \lambda b(T(z)) + A(T(z)).$$

Therefore, $\max_{T(y)=z} \{\lambda b(y) + A(y)\} = \lambda b(T(z)) + A(T(z))$. In this way we can take the corresponding inverse branch, say a_1 , and then, say a_2 , and we repeat all the way this choice again and again in order to define $a = (a_1, a_2, a_2, a_4, \dots) = (a_1, a_2, a_1, a_2, \dots)$. In this case a is an orbit of period two for σ and the claim is true. In the case $k = 3$, note that if $T^3(z) = z$, we have that $b(T^2(T(z))) = \lambda b(T^2(z)) + A(T^2(z))$ and $b(T(T(z))) = \lambda b(T(z)) + A(T(z))$, because $T(z)$ and $T^2(z)$ are in the support of μ_λ . In this way we follow a similar reasoning as before and we get an a which is an orbit of period 3 for the shift. Same thing for a periodic orbit with a general k . \square

As an example of the above, suppose $k = 2$, then there are two periodic orbits of period 3. Take one of them, let us say $\{z_1, z_2, z_3\}$. Suppose $T(z_1) = z_2, T(z_2) = z_3$ and $T(z_3) = z_1$. Given z_1 there exists

a_1 such that $\tau_{a_1}(z_1) = z_3$. Given z_3 there exists a_2 such that $\tau_{a_2}(z_3) = z_2$. Finally, given z_2 there exists a_3 such that $\tau_{a_3}(z_2) = z_1$. Then, in this case, $a = (a_1, a_2, a_3, a_1, a_2, a_3, a_1, \dots)$ is in the support of the dual periodic probability for $\{z_1, z_2, z_3\}$. The set $\{a, \sigma(a), \sigma^2(a)\}$ defines a periodic orbit of period 3 for the shift σ .

Definition 4. We denote by R the function $R = A - b \circ T + \lambda b \geq 0$ and call it the rate function.

For fixed λ , by the fiber contraction theorem [34] (section 5.12 page 202 and section 11.1 page 433) we get that the λ -calibrated subaction $b = b_{\lambda, A} = b_A$ is a continuous function of A in the C^0 topology. Moreover, the function $b = b_{\lambda, A}$ is a continuous function of A and λ .

Taking $\lambda \rightarrow 1$ will see now that we will get results which are useful for classical Ergodic Optimization.

We denote $m(A) = \sup\{\int A d\nu, \text{ among } T\text{-invariant probabilities } \nu\}$.

We call maximizing probability for A any ρ which attains the supremum $m(A)$. We denote any of these ρ by μ_A . A continuous function $U : S^1 \rightarrow \mathbb{R}$ is called a calibrated subaction for $A : S^1 \rightarrow \mathbb{R}$, if, for any $y \in S^1$, we have

$$(5) \quad U(y) = \max_{T(x)=y} [A(x) + U(x) - m(A)].$$

If $b_\lambda^{\&e} = b_\lambda - \max b_\lambda$, then, of course, μ_λ is maximizing for the rate function potential $A(x) - b_\lambda^{\&e}(T(z)) + \lambda b_\lambda^{\&e}(z)$. It is known (see [10] [27] [5] and [31]) that b_λ is equicontinuous in λ , and, any convergent subsequence, $\lambda_n \rightarrow 1$, satisfies $b_{\lambda_n}^{\&e} \rightarrow U$, where U is a calibrated subaction for A . Assuming the maximizing probability for A is **unique** (a generic property according to [11]), it is known (see [16] section 4), that when $\lambda \rightarrow 1$, we get that $b_\lambda^{\&e} \rightarrow U$, where U is a (the) calibrated subaction for A . In this way we can say that the family $b_\lambda^{\&e} \rightarrow U$ selects the calibrated subaction U . Assuming that the maximizing probability μ_A is unique, when $\lambda \rightarrow 1$, we get that \mathcal{B}_λ (after the subtraction of $\max b_\lambda$) converges to the graph of the calibrated subaction for A in the C^0 -topology. If the maximizing probability for A is not unique there exist several possible subactions. Anyway, the limit of any convergent subsequence \mathcal{B}_{λ_n} , $n \rightarrow \infty$, will be a set in $S^1 \times \mathbb{R}$, which is the graph of a subaction for A . Note that in any case it is true the relation: for any z

$$b^{\&e}(T(z)) - \lambda b^{\&e}(z) + (1 - \lambda)(\max b_\lambda) - A(z) \geq 0.$$

We point out that in classical Ergodic Optimization, given a Lipschitz potential $A : S^1 \rightarrow \mathbb{R}$, in order to obtain examples where one can

determine explicitly the maximizing probability or a calibrated subaction, it is necessary to know the exact value the maximal value $m(A)$ (see equation (5)). In the general case this is not an easy task and therefore any method of approximation of this maximal value or associated subaction is helpful. The discounted method provides approximations b_λ , $\lambda \in (0, 1)$, in the C^0 -topology, of calibrated subactions for A via the Banach fixed point theorem, that is, via a contraction in the set of continuous functions in the C^0 -topology. You take any function, iterate several times by the contraction and you will get a function \hat{b}_λ which is very close to the λ -calibrated subaction. If λ is close to 1, then, the corresponding $\hat{b}_\lambda^\&$ is close to a classical calibrated subaction U . In all this is not necessary to know the value $m(A)$. However, when λ becomes close to the value 1 this contraction becomes weaker and weaker.

Theorem 5 claims that for a generic potential A the maximizing measure for A is attained by a λ -maximizing probability for λ in an interval of the form $[1 - \epsilon, 1]$. Thanks to all that one can apply our reasoning for a λ is fixed and close to 1. In the discounted method taking $\lambda \sim 1$ the procedure also provides a way to approximate the value $m(A)$ as we will see later.

It is known (see [27]) that $(1 - \lambda)(\max b_\lambda) \rightarrow m(A)$. Then, as we said before, one can get an approximate value of $m(A)$ by the discounted method.

It is easy to see that close by the periodic points the graph of b is a piece of unstable manifold for F (see figure 4). We point out that for a generic Lipschitz potential A the maximizing probability for A is a unique periodic orbit (see [13]).

Now we state a result which is new in the literature.

Theorem 5. *If ν is a weak limit of a converging subsequence $\mu_{\lambda_n} \rightarrow \nu$, $\lambda_n \rightarrow 1$, then, ν is a maximizing probability for A . For a generic Lipschitz potential A there exist an ϵ , such that for all $\lambda \in (1 - \epsilon, 1]$, the λ -maximizing probability has support in the periodic orbit which defines the maximizing probability for A . If the potential A is of class C^1 the same is true on the C^1 topology.*

Proof. Consider a subsequence $\mu_{\lambda_n} \rightarrow \nu$, $\lambda_n \rightarrow 1$. Such ν is clearly invariant. Suppose by contradiction that for some $\epsilon > 0$ there exists an invariant μ such that $\int (A - U \circ T + U) d\nu + \epsilon < \int (A - U \circ T + U) d\mu$, then, for any n large enough we have

$$\int (A - b_{\lambda_n} \circ T + \lambda_n b_{\lambda_n}) d\mu_{\lambda_n} + \epsilon/2 < \int (A - b_{\lambda_n} \circ T + \lambda_n b_{\lambda_n}) d\mu,$$

and, we reach a contradiction.

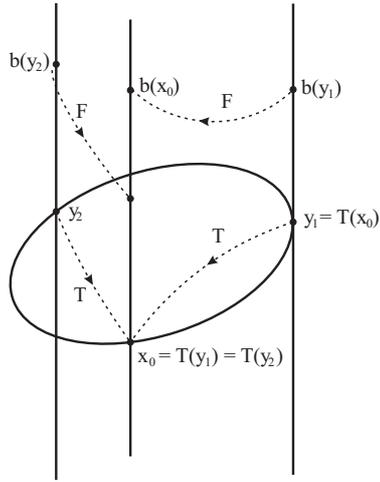

FIGURE 3. A geometric picture of the λ -calibrated property of b . The graph of b describes the upper boundary of the attractor.

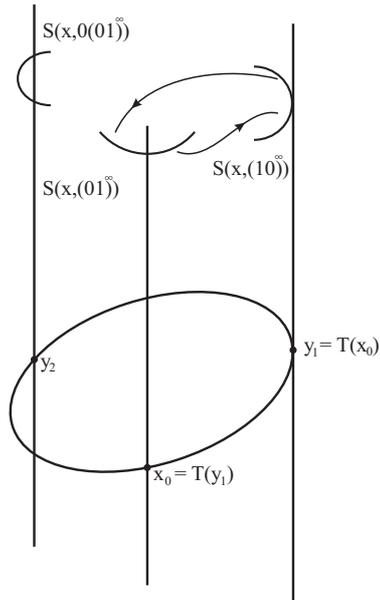

FIGURE 4. The unstable manifolds of a point of period two for F .

Now, for a generic potential it is known that the maximizing probability for A is a unique periodic orbit (see [13]). Therefore, $\mu_\lambda \rightarrow \nu$, when $\lambda \rightarrow 1$. From the continuous varying support (see [11]) if $\mu_\lambda \rightarrow \nu$ and ν is periodic orbit, then, there exist an $\epsilon > 0$ such that for $\lambda \in (1 - \epsilon, 1]$ the probability $\mu_\lambda = \nu$. If the potential A is of class

C^1 one can do the following: since μ_λ is maximizing for $A + (1 - \lambda)b$, which is Lipschitz-close to A , then, when λ is close to the value 1, we apply the continuous varying support property in order to get a Lipschitz subaction and perturb in the same way as in [13] in order to get an approximation by another Lipschitz potential with support in a unique periodic orbit. This potential can be approximated once more in the C^1 topology and again in his way by the continuous varying support we get C^1 potential with support in a periodic orbit. Then, the same formalism as above can be applied. \square

If $\mu_\lambda \rightarrow \mu_A$, when $\lambda \rightarrow 1$, we say that μ_λ selects the maximizing probability μ_A . In the present case for a generic A there is a selection via the discounted method.

Remark 6. *We point out the final conclusion: for a generic A we have that for λ close to 1 the maximizing probability μ_λ is a periodic orbit. Moreover, by Proposition 3 the realizer a for a point x in the support of μ_λ can be taken as a periodic orbit (with the same period) for the shift σ .*

An interesting example is $A(x) = -(x - 0.5)^2$ and $T(x) = 2x \pmod{1}$, which has a unique maximizing probability μ_A which is the one with support in the periodic orbit of period 2 according to Corollary 1.11 in [24] (see also [25]). Therefore, the corresponding λ -maximizing probability μ_λ converges to this one. In fact, there is an ϵ such that if $1 - \epsilon < \lambda < 1$, then μ_λ has support in this periodic orbit. This example will be carefully analyzed in the last sections of the paper.

3. THE λ -CALIBRATED SUBACTION AS AN ENVELOPE

Consider (as M. Tsujii in expression (3) page 1014 [36]) the function $S : (S^1, \Sigma) \rightarrow \mathbb{R}$, where $\Sigma = \{1, 2, \dots, d\}^{\mathbb{N}}$, given by

$$(6) \quad S_{\lambda,A}(x, a) = S(x, a) = \sum_{k=0}^{\infty} \lambda^k A(\tau_{k,a}x),$$

where $(\tau_{a_{k-1}} \circ \dots \circ \tau_{a_0})(x) = \tau_{k,a}x$ and $a = (a_0, a_1, a_2, \dots)$. For a fixed a the function $S_{\lambda,A}(\cdot, a)$ is continuous up to the point 0 (see several computer simulations in section 7 and the explicit expression for the quadratic case in subsection 7.4). Note that if A is of class C^2 , then for a fixed a the function $S(\cdot, a)$ is smooth up to the point 0 in S^1 , if $1 > \lambda > \frac{1}{d}$ (see in page 1014 the claim between expressions (3) and (4) in [36]).

We point out that the upper boundary of the attractor is periodic but each individual $S(x, a)$ as a function of x is not (see worked examples

in the end of the paper). Note also that for λ and a fixed the function $S_{\lambda,A}(\cdot, a)$ is linear in A . All x has a corresponding $a = a(x)$ such that $b(x) = S(x, a)$. Indeed, for the given x take i_0 such that $b(x) = \lambda b(\tau_{i_0}(x)) + A(\tau_{i_0}(x))$, then, take i_1 such that $b(\tau_{i_0}(x)) = \lambda b((\tau_{i_1} \circ \tau_{i_0})(x)) + A((\tau_{i_1} \circ \tau_{i_0})(x))$, and so on. In this way we get $a = (i_0, i_1, i_2, \dots)$. This a is not necessarily unique. We call any such possible $a(x)$ a **realizer for x** . Note that

$$\begin{aligned} b(x) &= \lambda [\lambda u((\tau_{i_1} \circ \tau_{i_0})(x)) + A((\tau_{i_1} \circ \tau_{i_0})(x))] + A(\tau_{i_0}(x)) = \\ &\lambda^2 u((\tau_{i_1} \circ \tau_{i_0})(x)) + \lambda A((\tau_{i_1} \circ \tau_{i_0})(x)) + A(\tau_{i_0}(x)) = \\ &\lambda^n u((\tau_{i_{n-1}} \circ \dots \circ \tau_{i_1} \circ \tau_{i_0})(x)) + \end{aligned}$$

$$\lambda^{n-1} A((\tau_{i_{n-1}} \circ \dots \circ \tau_{i_1} \circ \tau_{i_0})(x)) + \dots + \lambda A((\tau_{i_1} \circ \tau_{i_0})(x)) + A(\tau_{i_0}(x)).$$

Taking the limit when $n \rightarrow \infty$ we get $b(x) = S(x, a)$.

From the construction we claim that for any other $c \in \{1, 2, \dots, d\}^{\mathbb{N}}$ we have $b(x) \geq S(x, c)$. Indeed, consider $z(x) = \limsup_{n \in \mathbb{N}} \{ \lambda^{n-1} A((\tau_{i_{n-1}} \circ \dots \circ \tau_{i_1} \circ \tau_{i_0})(x)) + \dots + \lambda A((\tau_{i_1} \circ \tau_{i_0})(x)) + A(\tau_{i_0}(x)) \mid (i_0, i_1, \dots, i_{n-1}) \in \{1, 2, \dots, d\}^n \}$, and, the operator $\mathcal{L}_\lambda(v)(x) = \sup_{i=1,2,\dots,d} [A(\tau_i(x)) + \lambda v(\tau_i(x))]$.

Then, $\mathcal{L}_\lambda(z) = z$. It is known that b is a fixed point for \mathcal{L}_λ (see section 3 in [27], or section 2 in [5]). From the uniqueness of the fixed point it follows the claim. Therefore, we get from above the following result which we call the Envelope Theorem.

Theorem 7. $b(x) = b_{\lambda,A}(x) = \sup_{c \in \{1,2,\dots,d\}^{\mathbb{N}}} S(x, c) = S(x, a(x))$, where $a(x)$ is a realizer for x .

As the supremum of convex functions is convex we get that for λ fixed the function $b_{\lambda,A}$ varies in convex way with A .

Figure 2 suggests that $b(x)$ is obtained as $\sup\{S(x, w_1), S(x, w_2)\}$, where, w_1, w_2 , is in Σ . Later we will show that in several interesting examples w_1, w_2 are in a periodic orbit of period 2 for the shift σ . As we said before in the introduction we point out again here (in a more precise way) that Figure 1 in [36] suggests that $b(x)$ is obtained as $\sup\{S(x, w_i), i = 1, 2, 3, 4\}$, where, $w_i, i = 1, 2, 3, 4$, are in Σ . Note that the potential A in that case is conjectured to have a maximizing probability in an orbit of period 4 (see [14]).

Note that if A is of class C^2 , then, $S_a : (0, 1) \rightarrow \mathbb{R}$ is of class C^2 . We define $\pi(x) = i$, if x is in the image of $\tau_i(S^1 - \{0, 1\})$, $i \in \{1, 2, \dots, d\}$.

Note also (see (7) page 1014 in [36]) that $S(T(x), \pi(x)a) = A(x) + \lambda S(x, a)$. Or, in another way, for any $a = (a_0, a_1, \dots)$ we have that $S(x, a) = A(\tau_{a_0}(x)) + \lambda S(\tau_{a_0}(x), \sigma(a))$. This also means that $\phi(x, a) = (x, S(x, a))$ is a change of coordinates from F to $\mathbb{T}(x, a) = (T(x), \pi(x)a)$

[36]. $\mathbb{T}(x, a)$ is forward invariant in the upper boundary \mathcal{B} of the attractor. Note also that $\mathbb{T}^{-1}(x, a) = (\tau_{a_0}(x), \sigma(a))$ (when defined).

Definition 8. Consider a fixed $\bar{x} \in S^1$ and define

$$(7) \quad W(x, a) = S(x, a) - S(\bar{x}, a).$$

We call such W the λ -involution kernel for A .

Note that for a fixed $W(x, a)$ is smooth on $x \in (0, 1)$. From the above definition we get,

$$\begin{aligned} \lambda W(\tau_{a_0}(x), \sigma(a)) - W(x, a) &= \\ [\lambda S(\tau_{a_0}(x), \sigma(a)) - \lambda S(\bar{x}, \sigma(a))] - [S(x, a) - S(\bar{x}, a)] &= \\ [\lambda S(\tau_{a_0}(x), \sigma(a)) - S(x, a)] - [\lambda S(\bar{x}, \sigma(a)) - S(\bar{x}, a)] &= \\ -A(\tau_{a_0}(x)) + [\lambda S(\bar{x}, \sigma(a)) - S(\bar{x}, a)]. \end{aligned}$$

Note that $[\lambda S(\bar{x}, \sigma(a)) - S(\bar{x}, a)]$ just depend on a (not on x).

Definition 9. If we denote $A^*(a) = [\lambda S(\bar{x}, \sigma(a)) - S(\bar{x}, a)]$, we get the λ -coboundary equation: for any (x, a)

$$A^*(a) = A(\tau_{a_0}(x)) + [\lambda W(\tau_{a_0}(x), \sigma(a)) - W(x, a)].$$

We say that A^* is the λ -dual potential of A .

Note that A is defined for the variable $x \in S^1$ and A^* is defined for a which is in the dual space Σ . The above definition is similar to the one presented in [4], [29], [12] and [31]. Note that we have an explicit expression for the λ -involution kernel W which appears in the above definition.

Below we consider the lexicographic order in $\{1, \dots, d\}^{\mathbb{N}}$.

Definition 10. We say that A satisfies the twist condition, if an (then, any) associated involution kernel W , satisfies the property: for any $a < b$, we have

$$\frac{\partial W}{\partial x}(x, a) - \frac{\partial W}{\partial x}(x, b) > 0.$$

It is equivalent to state the above relation for S or for W . An important issue is described by Proposition 2.1 in [12] which basically says that (in our context) in the case W satisfies the twist property, then association x to a realizer $a(x)$ is monotone, where we use the lexicographic order in $\{1, \dots, d\}^{\mathbb{N}}$. See also Proposition 48 in the last section. This is not exactly, but very close, of saying that the support of the optimal plan probability for W is a graph. In [29] the question about the property of cyclically monotonicity (in the support) is addressed.

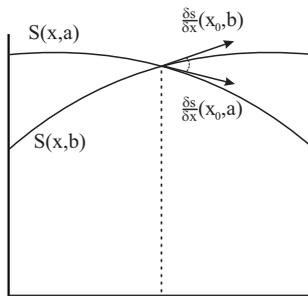

FIGURE 5. Under the twist condition the way the two graphs cut is compatible with the inequality $b < a$ (see Proposition 12).

4. GEOMETRY, COMBINATORICS OF THE GRAPHS OF $S(\cdot, a)$ AND THE TWIST CONDITION

Remember that $S(x, a) = \sum_{k=0} \lambda^k A(\tau_{k,a}x)$, and $W(x, a) = S(x, a) - S(\bar{x}, a)$. Moreover, one can get the calibrated subaction via the **superior envelope** $b(x) = b_{\lambda, A}(x) = \sup_{a \in \Sigma} S(x, a) = S(x, a(x))$. In this case $a(x) \in \Sigma$ is called an optimal symbolic element for x (possibly not unique). Under the twist condition, two graphs cut one each other in a compatible way with the inequality $a < b$. The envelope result, assures that, if the family $S(x, \cdot)$ is continuous in Σ , then $\frac{\partial b_{\lambda, A}}{\partial x}(x, a) = \frac{\partial S}{\partial x}(x, a)$, for every optimal a . Thus, if A is twist the optimal symbolic element is unique in every differentiable point of $b(x) = b_{\lambda, A}(x)$. **The two graphs on the Figure 5 can not cut twice by the twist property. This is the purpose of the next results. Note, however, that the graph of one $S(\cdot, c)$ will be intersected by an infinite number of other graphs of $S(\cdot, d)$.**

We will study now some additional properties of the family of maps $S(x, a)$. The first step is to consider some especial functions.

Definition 11. For a fixed pair $a, b \in \Sigma$ we define $\Delta : S^1 \times \Sigma \times \Sigma \rightarrow \mathbb{R}$ by $\Delta(x, a, b) = S(x, a) - S(x, b)$, that is C^2 smooth on $x \in (0, 1)$.

Computing this derivatives we get $\Delta'(x, a, b) = S'(x, a) - S'(x, b)$ and $\Delta''(x, a, b) = S''(x, a) - S''(x, b)$, thus we get two consequences. The first: if A is twist and $a \neq b$ then $\Delta'(x, a, b) \neq 0$, more precisely, if $a < b$ then $\Delta'(x, a, b) > 0$ else, if $a > b$ then $\Delta'(x, a, b) < 0$. The second consequence is for quadratic potentials, if A is quadratic then $A'' = cte$ and this implies that $\Delta''(x, a, b) = 0$, thus $\Delta(x, a, b) = \Delta(0, a, b) + x\Delta'(0, a, b)$, for $x \in S^1$. The twist property give us a certain geometric structure on the family $S(x, a)$. If we assume a is optimal for $x = 0$

and define $a^- = \{w \in \Sigma, w < a\}$ and $a^+ = \{w \in \Sigma, w > a\}$ we get the picture described by Figure 6.

Indeed, $\Delta(0, a, b) > 0$ and $\Delta'(x, a, b) > 0$ because $b > a$, thus $\Delta(x, a, b)$ is increasing what means that $S(x, a)$ and $S(x, b)$ has no intersection. On the other hand $c \in a^-$ which means that $\Delta'(x, a, b) < 0$ thus $S(x, c)$ can intersect $S(x, a)$ in just one point. Reciprocally, the

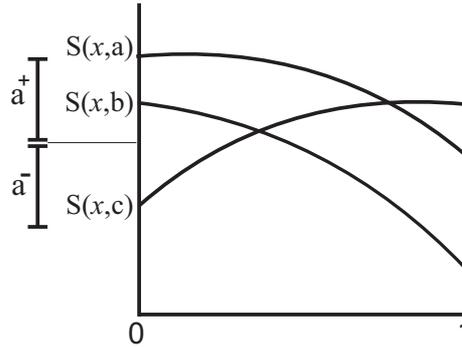

FIGURE 6. $b \in a^+$ and $c \in a^-$

twist property allow us to determinate the exact order of every three members a, b and c from the geometrical position of $S(x, a), S(x, b)$ and $S(x, c)$. We call this the triangle property; this means that if the corresponding positions are as in the Figure 7, then, we get that $a > c > b$.

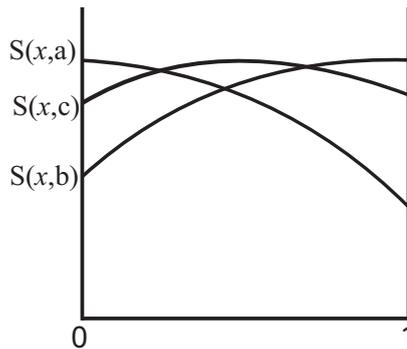

FIGURE 7. Triangle property.

Proposition 12. *Suppose S satisfies the twist condition for some fixed a and b , the positions of the graphs of $S(\cdot, a)$ and $S(\cdot, b)$ are described by figure 5. We assume x_0 is such that $0 = \Delta(x_0, a, b) = S(x_0, a) - S(x_0, b)$, then $\frac{\partial S}{\partial x}(x_0, a) < \frac{\partial S}{\partial x}(x_0, b)$.*

Proof. The proof follows from the fact that $\frac{\partial S}{\partial x}(x_0, a) - \frac{\partial S}{\partial x}(x_0, b) = \Delta'(x_0, a, b) < 0$. \square

The twist property assures a transversality condition on the intersections of the leaves described by the different graphs of $S(\cdot, a)$ (see beginning of section 4 in [36]). We point out that the twist condition was not explicitly considered in [36].

4.1. Invariance properties of the envelope. We already know that $b(x)$ given by $b_{\lambda, A}(x) = \sup_{a \in \Sigma} S(x, a) = S(x, a(x))$, is the upper envelope of the family $S(x, a)$. We remind the reader that the map \mathbb{T}^{-1} is defined by $\mathbb{T}^{-1}(x, a) = (\tau_{a_0}(x), \sigma(a))$. It is also well defined

$$S(x, a) = A(\tau_{a_0}(x)) + \lambda S(\tau_{a_0}(x), \sigma(a)).$$

We will prove that the upper envelope of the family $S(x, a)$ is invariant by \mathbb{T}^{-1} . Abusing of the notation we set $a(x)$ as **the set of such solutions for a given fixed x** ; $a(x)$ is indeed a multi function, that is, $b(x) = S(x, a)$, $\forall a \in a(x)$. We are going to prove that the first symbol in $a(x)$ uniquely determined by the symbol i_0 that turns out to be the maximum $b(x) = \max_i \{\lambda b(\tau_i x) + A(\tau_i x)\}$, more precisely, $b(x) = \lambda b(\tau_{i_0} x) + A(\tau_{i_0} x)$. We begin with a technical and crucial lemma.

Lemma 13. *The angle α between two transversal $S(x, a) = S(x, b)$ satisfy*

$$|\tan(\alpha)| = |\Delta'(x, a, b)| \leq \|A'\|_\infty \left(\frac{\lambda}{2}\right)^n \frac{2}{2-\lambda},$$

when $d(a, b) < \frac{1}{2^n}$. Therefore, if A is twist, then α is bounded away from zero.

Proof.

$$\begin{aligned} |\Delta'(x, a, b)| &= \left| \frac{\partial S}{\partial x}(x, a) - \frac{\partial S}{\partial x}(x, b) \right| = \left| \sum_{k=0}^{\infty} \lambda^k (A'(\tau_{k,a}x) - A'(\tau_{k,b}x)) \frac{1}{2^{k+1}} \right| \\ &\leq \frac{1}{2} \sum_{k=n}^{\infty} \left(\frac{\lambda}{2}\right)^k |A'(\tau_{k,a}x) - A'(\tau_{k,b}x)| \leq \|A'\|_\infty \sum_{k=n}^{\infty} \left(\frac{\lambda}{2}\right)^k = \\ &= \|A'\|_\infty \left(\frac{\lambda}{2}\right)^n \frac{1}{1-\frac{\lambda}{2}} = \|A'\|_\infty \left(\frac{\lambda}{2}\right)^n \frac{2}{2-\lambda}. \end{aligned}$$

\square

Remark 14. *Thus, if A is twist, there is a natural N_0 such that $S(x, a) = S(x, b)$ can only happen if $a_i \neq b_i$ for some $i < N_0$, that is, if they intersect one each other with an angle*

$$|\alpha| \geq \arctan \left(\|A'\|_\infty \left(\frac{\lambda}{2} \right)^{N_0} \frac{2}{2-\lambda} \right) > 0.$$

Corollary 15. *If A satisfy the twist condition then there exists finitely many points where the optimal symbolic changes. This shows that under the twist condition the boundary of the attractor is given by a finite number of pieces (of unstable manifolds).*

Proof. The claim follows from Lemma 13. If there is infinitely many different c such that $S(x, c_i) = S(x, c_j)$, then there exists $d(c_i, c_j) < \frac{1}{2^n}$, $\forall n \in \mathbb{N}$, but the angle is less than $\alpha_0 = \arctan \left(\|A'\|_\infty \left(\frac{\lambda}{2} \right)^{N_0} \frac{2}{2-\lambda} \right)$, which is a contradiction. \square

We point out that we do not need to take λ close to 1 for the above result. We just show that for any fixed λ and under the twist condition there exist a finite number of points c_j , $j = 1, 2, \dots, k$, such that

$$b(x) = \sup_{c \in \{1, 2, \dots, d\}^{\mathbb{N}}} S(x, c) = \sup_{j=1, 2, \dots, k} S(x, c_j).$$

A natural question is to ask about the nature of these points c_j , $j = 1, 2, \dots, k$. In the case the λ -maximizing probability is a unique periodic orbit and A is twist we will be able to describe some properties (see section 6). Some properties depend of the combinatorics of the position of the orbits (see Theorem 27). It can happen (see example below) that the λ -maximizing probability is a periodic orbit of period 2 and we need to use 3 points c_1, c_2, c_3 in the above equation (see figure 11).

Lemma 16. *If $b(x) = \lambda b(\tau_{i_0}x) + A(\tau_{i_0}x)$ then $i_0 * a(\tau_{i_0}x) \in a(x)$, where $*$ means the concatenation. Reciprocally, if $b(x) = S(x, c)$, then, $b(\tau_{c_0}x) = S(\tau_{c_0}x, \sigma c)$, and $b(x) = \lambda b(\tau_{c_0}x) + A(\tau_{c_0}x)$. In other words, if $b(x) = S(x, c)$ then the first symbol $i = c_0$ of c attains the supremum $b(x) = \max_i \{ \lambda b(\tau_i x) + A(\tau_i x) \}$.*

Proof. Suppose that $b(x) = \lambda b(\tau_{i_0}x) + A(\tau_{i_0}x)$ and $c \in a(\tau_{i_0}x)$, then $b(\tau_{i_0}x) = S(\tau_{i_0}x, c)$. An easy computation shows that $\lambda b(\tau_{i_0}x) + A(\tau_{i_0}x) = A(\tau_{i_0}x) + \lambda S(\tau_{i_0}x, c) = S(x, i_0 * c)$, so $b(x) = S(x, i_0 * c)$ which means that $i_0 * c \in a(x)$.

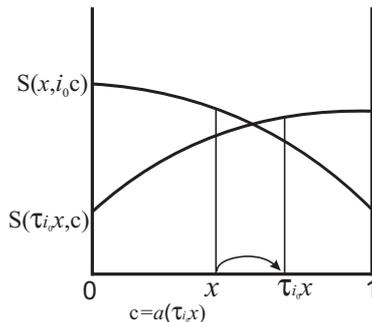

FIGURE 8

For the reciprocal suppose $b(x) = S(x, c) = A(\tau_{c_0}x) + \lambda S(\tau_{c_0}x, \sigma c)$. Since $b(x) = \max_i \{\lambda b(\tau_i x) + A(\tau_i x)\} \geq \lambda b(\tau_{c_0}x) + A(\tau_{c_0}x)$, we get,

$$A(\tau_{c_0}x) + \lambda S(\tau_{c_0}x, \sigma c) \geq \lambda b(\tau_{c_0}x) + A(\tau_{c_0}x),$$

which is equivalent to $b(\tau_{c_0}x) \leq S(\tau_{c_0}x, \sigma c)$, thus $b(\tau_{c_0}x) = S(\tau_{c_0}x, \sigma c)$. Substituting this in the previous equation we have that $b(x) = S(x, c) = A(\tau_{c_0}x) + \lambda b(\tau_{c_0}x)$. \square

If we suppose additionally that W satisfies the twist condition then, if $a(\tau_{i_0}x)$ is not a single point, then by Proposition 12, the function b is not differentiable at x because $b(x) = S(x, i_0 * c)$ and $b(x) = S(x, i_0 * d)$. However, $S'(x, i_0 * c) \neq S'(x, i_0 * d)$, if $c \neq d$, where $c, d \in a(\tau_{i_0}x)$.

Corollary 17. *The set $\Omega = \{(x, a) \in [0, 1] \times \Sigma \mid b(x) = S(x, a)\}$ is \mathbb{T}^{-1} -invariant.*

Proof. Indeed, if $(x, a) \in \Omega$ then $b(x) = S(x, a)$ and by Lemma 16 we have $b(\tau_{c_0}x) = S(\tau_{c_0}x, \sigma c)$. Thus $\mathbb{T}^{-1}(x, a) \in \Omega$. \square

Definition 18. *A crossing point $x = x_{ab}$ is the single point x satisfying $S(x, a) = S(x, b)$ with $a > b$.*

When A is twist, the crossing points are ordered according to the order of a, b and c as in the above figure. The explicit computable cases are very difficult to find, but we can present some computational evidence to illustrate the conclusion of Corollary 15.

Example 19. *Take $\varepsilon = 0.005$, $\lambda = 0.51$, $drift = 0.05$ and $gap = 0.001$, we use a truncated version $S(x, a) = \sum_{k=0}^7 \lambda^k A(\tau_{k,a}x)$ where $A(x) := A_\varepsilon(x) = -(1.010x - 0.455)^2$ is a perturbation of $-(x - 0.5)^2$ by $A_\varepsilon(x) = -(x - 0.5 + \varepsilon\phi(x) + drift)^2$ and $\phi(x) = 2x - 1$. The figure below shows the maximum $b(x) = \max_a S(x, a)$ in a grid of 25 divisions of $[0, 1]$, and suggest the form of the graph of b in the figure 10. This*

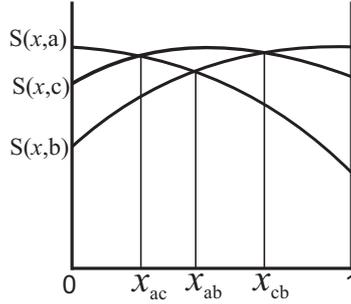

FIGURE 9

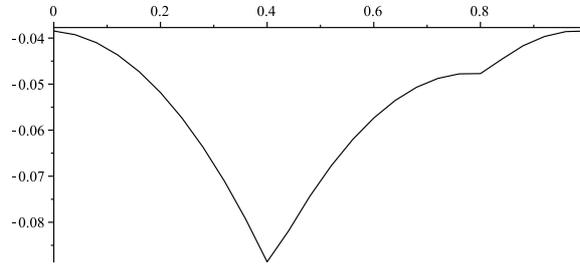

FIGURE 10

figure suggest that there is 3 pieces $S(x, 10101\dots)$, $S(x, 01010\dots)$ and a unknown $S(x, c_0c_1c_2\dots)$. Since the disturbed potential still having the twist property we get $c_0 = 0$. Taking x in the right side of de second crossing point v we get $b(x) = S(x, c_0 * \sigma c)$ and from Corollary 17 we get $b(\tau_{c_0}x) = S(\tau_{c_0}x, \sigma c)$, in particular $b(\tau_{c_0}x) = b(\tau_0x)$ lies in the right side of the first crossing point u because the first symbol of the optimal sequences for points before u is 1. Therefore, σc should be $(0101\dots)$. From this hypothetic deductions we can suppose that, if u and v are the crossing points, then the formula for the superior envelop $b(x)$ should be

$$b(x) := \begin{cases} S(x, 101010\dots) & , \quad 0 < x \leq u \\ S(x, 010101\dots) & , \quad u < x \leq v \\ S(x, 001010\dots) & , \quad v < x \leq 1 \end{cases}$$

This is exactly what the Figure 11 shows, that is, we already know from Lemma 16 that there is only a finite number of pieces, we just deduce now what are the geometric positions of these pieces. In the graph we plot $b(x) + \text{gap} = b(x) + 0.001$ in order to distinguish the difference between this and the picture computationally obtained. If we iterate some orbits close to the attractor by the transformation

$F(x, s) = (T(x), \lambda s + A(x))$, we can see that there is numerical evidence that our claim is true in this particular case.

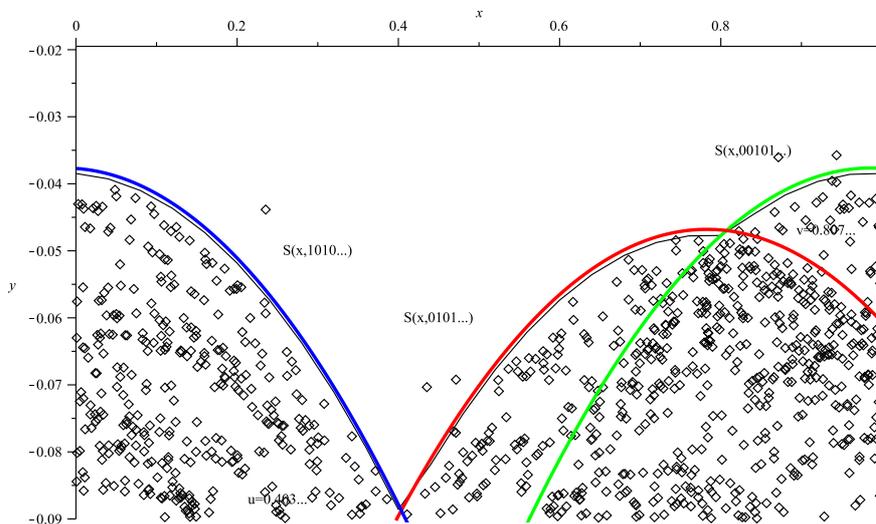

FIGURE 11. Iteration by 4000 times of F .

Definition 20. A turning point is a point x such that $b(x) = \lambda b(\tau_{i_0}x) + A(\tau_{i_0}x)$ for more than one symbol i_0 .

The concept of turning point was introduced in [12] and [30]. Denote by \mathcal{T} the set of turning points and $\Lambda = \cup_{n \geq 0} T^n(\mathcal{T})$. In order to characterize the turning points we follow a discounted version of the notation introduced by [9] for Sturmian measures when the symbols are $\{0, 1\}$.

Definition 21. If $b(x) = \max_i \{\lambda b(\tau_i x) + A(\tau_i x)\}$, we define the remainders associated with the b and A as $r(x, a) = b(x) - \lambda b(\tau_{a_0}x) - A(\tau_{a_0}x)$,

$$R(x) = r(x, 0 \cdots) - r(x, 1 \cdots) = (\lambda b(\tau_1 x) + A(\tau_1 x)) - (\lambda b(\tau_0 x) + A(\tau_0 x)).$$

So, $r(x, a) \geq 0$ and attains zero with the right symbol a_0 . Also, $R(x) = 0$, if and only if, x is a turning point that is, $\mathcal{T} = R^{-1}(0)$.

Definition 22. A continuous potential A satisfy the k -Sturmian condition if $\#R^{-1}(0) = k$. In particular, there is just k turning points.

In [9] Sturmian measures are that ones where $k = 1$. In a slightly different setting the author shows that $A(x) = \cos(2\pi(x - \omega))$ satisfy the 1-Sturmian condition for any $\omega \in \mathbb{R}/\mathbb{Z}$.

Lemma 23. Λ contains the set of points x where $a(x)$ is not a single point.

Proof. Suppose that there is two different elements $c, d \in a(x)$ and $c = (i_0, i_1, \dots, i_{n-1}, 1, c_{n+1}, \dots)$, $d = (i_0, i_1, \dots, i_{n-1}, 0, d_{n+1}, \dots)$. Take $z = \tau_{i_{n-1}} \cdots \tau_{i_0} x$. Applying Corollary 17 we get:

$$\begin{aligned} c \in a(x) &\Rightarrow b(x) = S(x, c) \Rightarrow b(\tau_{i_0} x) = S(\tau_{i_0} x, \sigma c) \cdots \\ &\Rightarrow b(\tau_{i_1} \tau_{i_0} x) = S(\tau_{i_1} \tau_{i_0} x, \sigma^2 c) \cdots \Rightarrow b(z) = S(z, (1, c_{n+1}, \dots)). \\ d \in a(x) &\Rightarrow b(x) = S(x, d) \Rightarrow b(\tau_{i_0} x) = S(\tau_{i_0} x, \sigma d) \cdots \Rightarrow \\ &\Rightarrow b(\tau_{i_1} \tau_{i_0} x) = S(\tau_{i_1} \tau_{i_0} x, \sigma^2 d) \cdots \Rightarrow b(z) = S(z, (0, d_{n+1}, \dots)). \end{aligned}$$

Thus, $b(z) = \lambda b(\tau_0 z) + A(\tau_0 z)$ and $b(z) = \lambda b(\tau_1 z) + A(\tau_1 z)$, by Lemma 16, that is, $z \in \mathcal{T}$. Since $T^n(z) = x$ we get $x \in \Lambda$. \square

If the turning points are finite (A satisfying k -Sturmian condition) and pre-periodic points for T , then there exists finitely many points where the optimal symbolic changes because $\#\Lambda < \infty$.

Corollary 24. If $\#\Lambda$ is finite then the graph of b is a union of a finite number of $S(x, a)$.

Proof. The claim follows from Lemma 23. \square

5. SYMMETRIC TWIST POTENTIALS

In this section we exhibit some explicit examples.

Theorem 25. Let A be a symmetric potential, that is, $A(1-x) = A(x)$ for any $x \in [0, 1]$. In addition we assume that A is twist. Denote by $b : [0, 1] \rightarrow \mathbb{R}$ the function such that

$$b(x) = \begin{cases} S(x, (10)^\infty), & 0 \leq x \leq 1/2; \\ S(x, (01)^\infty), & 1/2 < x \leq 1. \end{cases}$$

Then, b is a λ -calibrated subaction for $A(x)$, that is, for any $x \in [0, 1]$

$$b(x) = \max_{i=0,1} \{ \lambda b(\tau_i x) + A(\tau_i x) \}.$$

Proof. As A is symmetric $A(1/2 - t) = A(1/2 + t)$ for $t \in [0, 1/2]$. We claim that $S(x, (10)^\infty) = S((1-x), (01)^\infty)$. Indeed

$$\tau_0(1-x) = \frac{1-x}{2} = 1/2 - x/2 \text{ and } \tau_1(x) = \frac{1+x}{2} = 1/2 + x/2,$$

then, $A(\tau_0(1-x)) = A(\tau_1(x))$. Analogously, $\tau_1 \tau_0(1-x) = 1/4 - x/4 + 1/2$ and $\tau_0 \tau_1(x) = \frac{1+x}{2} = 1/4 + x/4 = 1/2 - (1/4 - x/4)$, then $A(\tau_1 \tau_0(1-x)) = A(\tau_0 \tau_1(x))$, and so on. Thus

$$S(x, (10)^\infty) = A(\tau_1(x)) + \lambda A(\tau_0 \circ \tau_1(x)) + \lambda^2 A(\tau_1 \circ \tau_0 \circ \tau_1(x)) + \dots =$$

$$A(\tau_0(1-x)) + \lambda A(\tau_1\tau_0(1-x)) + \lambda^2 A(\tau_0\circ\tau_1\circ\tau_0(1-x)) + \dots = S((1-x), (01)^\infty).$$

In particular, $S(0, (10)^\infty) = S(1, (01)^\infty)$ and $S(1/2, (10)^\infty) = S(1/2, (01)^\infty)$, that is $b(x)$ is continuous. By the twist property $S(x, (10)^\infty)$ and $S(x, (01)^\infty)$ are transversal in $x = 1/2$, then, as can not exist two points of intersection we get

$$\begin{aligned} S(x, (10)^\infty) &> S(x, (01)^\infty) \text{ if } x < 1/2; \\ S(x, (10)^\infty) &< S(x, (01)^\infty) \text{ if } x > 1/2. \end{aligned}$$

Now we will prove that the above b is a λ -calibrated subaction for $A(x)$.

We divide the argument in two cases:

Case 1- $x < 1/2$

If $i = 0$ then

$$\begin{aligned} \lambda b(\tau_i x) + A(\tau_i x) &= A(\tau_0 x) + \lambda b(\tau_0 x) \\ &= A(\tau_0 x) + \lambda S(\tau_0 x, (10)^\infty) \\ &= S(x, (01)^\infty) < S(x, (10)^\infty) \end{aligned}$$

because $x < 1/2$.

If $i = 1$ then

$$\begin{aligned} \lambda b(\tau_i x) + A(\tau_i x) &= A(\tau_1 x) + \lambda b(\tau_1 x) \\ &= A(\tau_1 x) + \lambda S(\tau_1 x, (01)^\infty) \\ &= S(x, (10)^\infty) \end{aligned}$$

because $\tau_1 x > 1/2$.

Thus, $\max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\} = S(x, (10)^\infty) = b(x)$ if $x < 1/2$.

Case 2- $x > 1/2$

If $i = 0$ then

$$\begin{aligned} \lambda b(\tau_i x) + A(\tau_i x) &= A(\tau_0 x) + \lambda b(\tau_0 x) \\ &= A(\tau_0 x) + \lambda S(\tau_0 x, (10)^\infty) \\ &= S(x, (01)^\infty) \end{aligned}$$

because $\tau_0 x < 1/2$. If $i = 1$ then

$$\begin{aligned} \lambda b(\tau_i x) + A(\tau_i x) &= A(\tau_1 x) + \lambda b(\tau_1 x) \\ &= A(\tau_1 x) + \lambda S(\tau_1 x, (01)^\infty) \\ &= S(x, (10)^\infty) < S(x, (01)^\infty) \end{aligned}$$

because $x > 1/2$. Thus, $\max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\} = S(x, (01)^\infty) = b(x)$ if $x > 1/2$. \square

It follows from above that in this case the λ -calibrated subaction is piecewise differentiable if A is differentiable. It is piecewise analytic (two domains of analyticity) if A is analytic.

6. A CHARACTERIZATION OF WHEN THE BOUNDARY IS PIECEWISE SMOOTH IN THE CASE OF PERIOD 2 AND 3

We will present a characterization of when the boundary is piecewise smooth in the case the λ -maximizing probability has period 2 and 3 (see Theorem 27). As we know that a λ -calibrated subaction for $A(x)$, that is, for any $x \in [0, 1]$ $b(x) = \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}$, is unique and $\bar{b}(x) = \sup_{a \in \{0,1\}^{\mathbb{N}}} S(x, a)$, is also a solution of this equation, we get that the superior envelope of $\{S(x, a) \mid a \in \{0, 1\}^{\mathbb{N}}\}$ is piecewise regular as much as A .

Lemma 26. *If $0 < x < y < 1$ and $S(x, a') = \sup_{a \in \{0,1\}^{\mathbb{N}}} S(x, a)$ and $S(y, a'') = \sup_{a \in \{0,1\}^{\mathbb{N}}} S(y, a)$ then there is $x < z < y$ such that $S(z, a') = S(z, a'')$. In particular, from the twist property, $a' > a''$ and*

$$\begin{aligned} S(x, a') &> S(x, a'') \text{ if } x < z; \\ S(x, a') &< S(x, a'') \text{ if } x > z. \end{aligned}$$

We assume here that $T(x)$ is the transformation $2x \pmod{1}$. Now we going to consider the case where the maximizing measure is supported in a periodic orbit of period 3. We know that if the minimum period is 3 there is just two possible periodic sequences: $(100100100\dots) = (100)^\infty$ and $(110110110\dots) = (110)^\infty$. We choose the case $(110110110\dots) = (110)^\infty$ with the correspondent periodic point $x_0 = 3/7 < T^2(x_0) = 5/7 < T(x_0) = 6/7$.

Theorem 27. *Let A be a twist potential such that $S(x_0, (110)^\infty) = \sup_{a \in \{0,1\}^{\mathbb{N}}} S(x_0, a)$, $S(T(x_0), (011)^\infty) = \sup_{a \in \{0,1\}^{\mathbb{N}}} S(T(x_0), a)$, $S(T^2(x_0), (101)^\infty) = \sup_{a \in \{0,1\}^{\mathbb{N}}} S(T^2(x_0), a)$, where $T^3(x_0) = x_0$. Let $u \in [x_0, T^2(x_0)]$ and $v \in [T^2(x_0), T(x_0)]$ given by Lemma 26, that is, $S(u, (110)^\infty) = S(u, (101)^\infty)$ and $S(v, (101)^\infty) = S(v, (011)^\infty)$. Denote by $b : [0, 1] \rightarrow \mathbb{R}$ the function such that*

$$b(x) = \begin{cases} S(x, (110)^\infty), & 0 \leq x \leq u; \\ S(x, (101)^\infty), & u \leq x \leq v; \\ S(x, (011)^\infty), & v \leq x \leq 1. \end{cases}$$

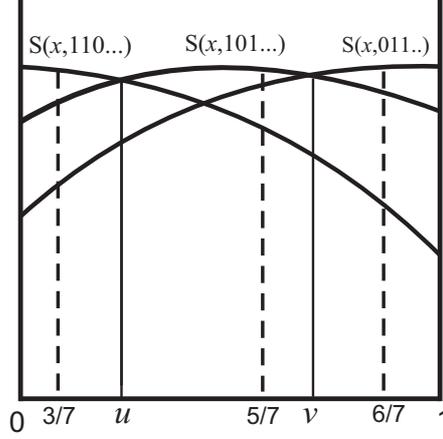

FIGURE 12

Then, b is a λ -calibrated subaction for $A(x)$, that is, for any $x \in [0, 1]$ $b(x) = \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}$, if and only if, $\tau_1[0, u] \subseteq [u, v]$, $\tau_1[u, v] \subseteq [v, 1]$ and $\tau_0[v, 1] \subseteq [0, u]$.

Proof. We must to divide in several cases.

Case 1: Consider $0 \leq x \leq u$.

As $\tau_0(x) = 1/2x < u$ thus

$$\begin{aligned} \lambda b(\tau_0 x) + A(\tau_0 x) &= \lambda S(\tau_0 x, (110)^\infty) + A(\tau_0 x) = \\ &= \lambda S(\tau_0 x, (110)^\infty) + A(\tau_0 x) = S(x, 0(110)^\infty) = \\ &= S(x, (011)^\infty) < S(x, (110)^\infty) = b(x) \end{aligned}$$

As $\tau_1(x) = 1/2x + 1/2 > u$ we have two possibilities

a) If $\tau_1(x) \in (u, v]$ then

$$\begin{aligned} \lambda b(\tau_1 x) + A(\tau_1 x) &= \lambda S(\tau_1 x, (101)^\infty) + A(\tau_1 x) = \\ &= \lambda S(\tau_1 x, (101)^\infty) + A(\tau_1 x) = S(x, 1(101)^\infty) = \\ &= S(x, (110)^\infty) = b(x) \end{aligned}$$

b) If $\tau_1(x) \in [v, 1]$ then

$$\begin{aligned} \lambda b(\tau_1 x) + A(\tau_1 x) &= \lambda S(\tau_1 x, (011)^\infty) + A(\tau_1 x) = \\ &= \lambda S(\tau_1 x, (011)^\infty) + A(\tau_1 x) = S(x, 1(011)^\infty) = \\ &= S(x, (101)^\infty) < S(x, (110)^\infty) = b(x). \end{aligned}$$

Thus

$$b(x) \begin{cases} = \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}, & \text{if } \tau_1[0, u] \subseteq [u, v] \\ < \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}, & \text{otherwise.} \end{cases}$$

for $0 \leq x \leq u$.

Case 2: Consider $u \leq x \leq v$.

As $\tau_0(x) = 1/2x < v$ we have two possibilities

a) If $\tau_0(x) \in [0, u]$ then

$$\begin{aligned} \lambda b(\tau_0 x) + A(\tau_0 x) &= \lambda S(\tau_0 x, (110)^\infty) + A(\tau_0 x) = \\ &= \lambda S(\tau_0 x, (110)^\infty) + A(\tau_0 x) = S(x, 0(110)^\infty) = \\ &= S(x, (011)^\infty) < S(x, (101)^\infty) = b(x) \end{aligned}$$

b) If $\tau_0(x) \in [u, v]$ then

$$\begin{aligned} \lambda b(\tau_0 x) + A(\tau_0 x) &= \lambda S(\tau_0 x, (101)^\infty) + A(\tau_0 x) = \\ &= \lambda S(\tau_0 x, (101)^\infty) + A(\tau_0 x) = S(x, 0(101)^\infty) = \\ &= S(x, 0(101)^\infty) < S(x, (101)^\infty) = b(x), \end{aligned}$$

because $S(x, 0(101)^\infty) > S(x, (101)^\infty)$ contradicts the twist condition, as one can see from the Figure 13. As $\tau_1(x) \in [5/7, 6/7]$ we have two

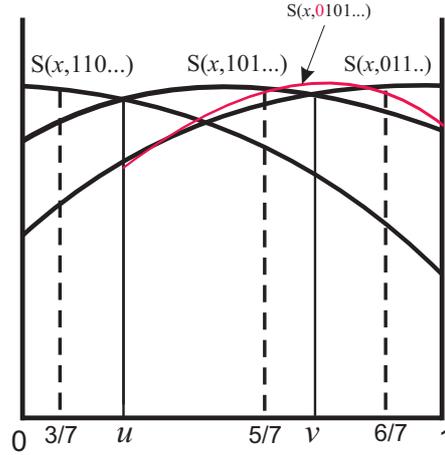

FIGURE 13

possibilities

a) If $\tau_1(x) \in [u, v]$ then

$$\begin{aligned} \lambda b(\tau_1 x) + A(\tau_1 x) &= \lambda S(\tau_1 x, (101)^\infty) + A(\tau_1 x) = \\ &= \lambda S(\tau_1 x, (101)^\infty) + A(\tau_1 x) = S(x, 1(101)^\infty) = \\ &= S(x, (110)^\infty) < S(x, (101)^\infty) = b(x). \end{aligned}$$

b) If $\tau_1(x) \in [v, 1]$ then

$$\begin{aligned} \lambda b(\tau_1 x) + A(\tau_1 x) &= \lambda S(\tau_1 x, (011)^\infty) + A(\tau_1 x) = \\ &= \lambda S(\tau_1 x, (011)^\infty) + A(\tau_1 x) = S(x, 1(011)^\infty) = \\ &= S(x, (101)^\infty) = b(x). \end{aligned}$$

Thus

$$b(x) \begin{cases} = \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}, & \text{if } \tau_1[u, v] \subseteq [v, 1] \\ < \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}, & \text{otherwise.} \end{cases}$$

for $u \leq x \leq v$.

Case 3: Consider $v \leq x \leq 1$.

As $\tau_0(x) = 1/2x < 1/2$ we have two possibilities

a) If $\tau_0(x) \in [0, u]$ then

$$\begin{aligned} \lambda b(\tau_0 x) + A(\tau_0 x) &= \lambda S(\tau_0 x, (110)^\infty) + A(\tau_0 x) = \\ &= \lambda S(\tau_0 x, (110)^\infty) + A(\tau_0 x) = S(x, 0(110)^\infty) = \\ &= S(x, (011)^\infty) = b(x). \end{aligned}$$

b) If $\tau_0(x) \in [u, v]$ then

$$\begin{aligned} \lambda b(\tau_0 x) + A(\tau_0 x) &= \lambda S(\tau_0 x, (101)^\infty) + A(\tau_0 x) = \\ &= \lambda S(\tau_0 x, (101)^\infty) + A(\tau_0 x) = S(x, 0(101)^\infty) = \\ &= S(x, 0(101)^\infty) < S(x, (011)^\infty) = b(x), \end{aligned}$$

because $S(x, 0(101)^\infty) > S(x, (011)^\infty)$ contradicts the twist (as one can see from Figure 13).

As $\tau_1(x) \in [v, 1]$ we have

$$\begin{aligned} \lambda b(\tau_1 x) + A(\tau_1 x) &= \lambda S(\tau_1 x, (011)^\infty) + A(\tau_1 x) = \\ &= \lambda S(\tau_1 x, (011)^\infty) + A(\tau_1 x) = S(x, 1(011)^\infty) = \\ &= S(x, (101)^\infty) < S(x, (011)^\infty) = b(x). \end{aligned}$$

Thus

$$b(x) \begin{cases} = \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}, & \text{if } \tau_0[v, 1] \subseteq [0, u] \\ < \max_{i=0,1} \{\lambda b(\tau_i x) + A(\tau_i x)\}, & \text{otherwise.} \end{cases}$$

for $v \leq x \leq 1$.

□

The characterization in the case the maximizing measure has support in an orbit of period n is similar. One needs to know the combinatorics of the position of the different points of the orbit and then proceed in an analogous way as in the case of period 3. We left this to the reader.

7. TWIST PROPERTIES IN THE CASE $T(x) = 2x \pmod{1}$

Let us fix $a = (a_0, a_1, \dots) \in \{0, 1\}^{\mathbb{N}}$. If A is differentiable we can differentiate S with respect to x

$$\frac{\partial S}{\partial x}(x, a) = \sum_{k=0}^{\infty} \lambda^k A'(\tau_{k,a}x) \frac{\partial}{\partial x} \tau_{k,a}x.$$

We observe that $\tau_{k,a}x$ has an explicit expression: $\tau_{k,a}x = \frac{1}{2^{k+1}}x + \psi_k(a)$, where

$$\psi_k(a) = \frac{a_0}{2^{k+1}} + \frac{a_1}{2^k} + \dots + \frac{a_k}{2},$$

satisfy the recurrence relation $2\psi_{k+1}(a) = \psi_k(a) + a_{k+1}$. Thus

$$\frac{\partial S}{\partial x}(x, a) = \sum_{k=0}^{\infty} \lambda^k A'(\tau_{k,a}x) \frac{1}{2^{k+1}} = \frac{1}{2} \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k A'(\tau_{k,a}x).$$

Analogously,

$$\frac{\partial^2 S}{\partial x^2}(x, a) = \sum_{k=0}^{\infty} \lambda^k A''(\tau_{k,a}x) \frac{1}{2^{k+1}}^2 = \frac{1}{4} \sum_{k=0}^{\infty} \left(\frac{\lambda}{4}\right)^k A''(\tau_{k,a}x),$$

in particular, if $A'' < 0$ then $\frac{\partial^2 S}{\partial x^2}(x, a) < 0, \forall a \in \Sigma$. Even if A is not C^2 we have the concavity of S from A :

Lemma 28. *Let A be a C^0 potential in S^1 . If A is concave (strictly) then $S(x, a)$ is concave (strictly), $\forall a \in \Sigma$.*

Proof. Fixed $a \in \Sigma$ consider $x < y$ and $t \in [0, 1]$ then

$$S((1-t)x + ty, a) = \sum_{k=0}^{\infty} \lambda^k A(\tau_{k,a}[(1-t)x + ty]).$$

Since $\tau_{k,a}(1-t)x + ty = \frac{1}{2^{k+1}}[(1-t)x + ty] + \psi_k(a) = (1-t)\tau_{k,a}x + t\tau_{k,a}y$, we get

$$\begin{aligned} S((1-t)x + ty, a) &= \sum_{k=0}^{\infty} \lambda^k A((1-t)\tau_{k,a}x + t\tau_{k,a}y) \geq \\ &\geq \sum_{k=0}^{\infty} \lambda^k [(1-t)A(\tau_{k,a}x) + tA(\tau_{k,a}y)] = (1-t)S(x, a) + tS(y, a). \end{aligned}$$

□

7.1. Formal Computations. First we prove two technical lemmas about recursive sums.

Lemma 29. *Let $\psi_k(a)$ be the function defined above, then*

$$\sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k \psi_k(a) = \frac{2}{4-\lambda} Z(a),$$

where $Z(a) = \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k a_k$.

Proof. Consider $H = \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k \psi_k(a)$ then

$$\begin{aligned} 2H &= 2 \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k \psi_k(a) \\ &= 2\psi_0(a) + \sum_{k=1}^{\infty} \left(\frac{\lambda}{2}\right)^k 2\psi_k(a) \\ &= a_0 + \sum_{k=1}^{\infty} \left(\frac{\lambda}{2}\right)^k [\psi_{k-1}(a) + a_k] \\ &= a_0 + \sum_{k=1}^{\infty} \left(\frac{\lambda}{2}\right)^k \psi_{k-1}(a) + \sum_{k=1}^{\infty} \left(\frac{\lambda}{2}\right)^k a_k \\ &= \frac{\lambda}{2} \sum_{k=1}^{\infty} \left(\frac{\lambda}{2}\right)^{k-1} \psi_{k-1}(a) + \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k a_k \\ &= \frac{\lambda}{2} \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k \psi_k(a) + \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k a_k \\ &= \frac{\lambda}{2} H + Z(a). \end{aligned}$$

Thus, $H = \frac{2}{4-\lambda} Z(a)$, where $Z(a) = \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k a_k$ is the expansion in the bases $\frac{2}{\lambda}$ of the number $Z(a)$. \square

Lemma 30. *If $\lambda < 1$ the function $Z : \Sigma \rightarrow [0, 1]$ given by $Z(a) = \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k a_k$ is strictly increasing with respect to the lexicographical order. In particular, if $b > a$ then*

$$Z(b) - Z(a) \geq \left(\frac{\lambda}{2}\right)^n \left(\frac{1-\lambda}{1-\frac{\lambda}{2}}\right),$$

where n is the first digit where a is different from b .

Proof. Take

$$a = (i_0, \dots, i_{n-1}, 0, a_{n+1}, i_{n+2}, \dots) < b = (i_0, \dots, i_{n-1}, 1, b_{n+1}, b_{n+2}, \dots),$$

then,

$$\begin{aligned} Z(b) - Z(a) &= \left(\frac{\lambda}{2}\right)^n (1 - 0) + \sum_{k=n+1}^{\infty} \left(\frac{\lambda}{2}\right)^k (b_k - a_k) \geq \\ &\geq \left(\frac{\lambda}{2}\right)^n - \sum_{k=n+1}^{\infty} \left(\frac{\lambda}{2}\right)^k = \left(\frac{\lambda}{2}\right)^n - \frac{(\frac{\lambda}{2})^{n+1}}{1 - \frac{\lambda}{2}} = \\ &= \left(\frac{\lambda}{2}\right)^n \left(1 - \frac{\frac{\lambda}{2}}{1 - \frac{\lambda}{2}}\right) = \left(\frac{\lambda}{2}\right)^n \left(\frac{1 - \lambda}{1 - \frac{\lambda}{2}}\right) > 0 \end{aligned}$$

□

We are going now to compute $\frac{\partial S}{\partial x}(x, a)$ for x^m for $m = 0, 1, 2$.¹

a) $A(x) = 1$

In that case, $S_1(x, a) = \sum_{k=0}^{\infty} \lambda^k 1 = \frac{1}{1-\lambda}$, so $\frac{\partial S}{\partial x}(x, a) = 0$.

b) $A(x) = x$

In that case,

$$S_x(x, a) = \sum_{k=0}^{\infty} \lambda^k \tau_{k,a} x, \text{ so } \frac{\partial S}{\partial x}(x, a) = \frac{1}{2} \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k = \frac{1}{2-\lambda}.$$

c) $A(x) = x^2$

In that case,

$$S_{x^2}(x, a) = \sum_{k=0}^{\infty} \lambda^k (\tau_{k,a} x)^2,$$

$$\text{so } \frac{\partial S}{\partial x}(x, a) = \frac{1}{2} \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k 2(\tau_{k,a} x) = \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k (\tau_{k,a} x). \text{ Thus,}$$

$$\begin{aligned} \frac{\partial S}{\partial x}(x, a) &= \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k \left[\frac{1}{2^{k+1}} x + \psi_k(a) \right] \\ &= \frac{x}{2} \sum_{k=0}^{\infty} \left(\frac{\lambda}{4}\right)^k + \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k \psi_k(a) \\ &= \frac{2}{4-\lambda} x + \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k \psi_k(a) \end{aligned}$$

¹This potentials are actually defined in \mathbb{R} because they are not continuous functions on S^1 , but some combination of $1, x, x^2, \dots$ allow us to build an 1-periodic function

Applying Lemma 29 we have

$$\frac{\partial S_{x^2}}{\partial x}(x, a) = \frac{2}{4-\lambda}x + \frac{2}{4-\lambda}Z(a).$$

Theorem 31. *If $A(x) = c_0 + c_1x + c_2x^2$ is 1-periodic differentiable in $S^1 - \{0\}$ then*

$$\frac{\partial S}{\partial x}(x, a) = \left(\frac{c_1}{2-\lambda} + \frac{2c_2}{4-\lambda}x \right) + \frac{2c_2}{4-\lambda}Z(a).$$

Moreover, A is twist if and only if $c_2 < 0$.

Proof. Using the notation $S_A(x, a) = \sum_{k=0}^{\infty} \lambda^k A(\tau_{k,a}x)$, one can easily show that S depends linearly of A . So if we have, $A(x) = c_0 + c_1x + c_2x^2$, then

$$S_A(x, a) = c_0 \cdot S_1(x, a) + c_1 S_x(x, a) + c_2 S_{x^2}(x, a).$$

We also can compute $\frac{\partial S}{\partial x}(x, a)$,

$$\frac{\partial S}{\partial x}(x, a) = c_0 \cdot 0 + c_1 \frac{1}{2-\lambda} + c_2 \left(\frac{2}{4-\lambda}x + \frac{2}{4-\lambda}Z(a) \right),$$

or

$$\frac{\partial S}{\partial x}(x, a) = \left(\frac{c_1}{2-\lambda} + \frac{2c_2}{4-\lambda}x \right) + \frac{2c_2}{4-\lambda}Z(a).$$

Moreover,

$$\frac{\partial S}{\partial x}(x, a) - \frac{\partial S}{\partial x}(x, b) = \frac{2c_2}{4-\lambda}(Z(a) - Z(b)).$$

Remember that, if $a > b$ then $Z(a) - Z(b) > 0$ (by Lemma 30). In this way, $\frac{\partial S}{\partial x}(x, a) - \frac{\partial S}{\partial x}(x, b) < 0$, if and only, if $c_2 < 0$. \square

Suppose that A is such that the λ -maximizing probability has period 2 and the subaction b_λ is the envelope of $S(x, (0, 1, 0, 1, \dots))$ and $S(x, (1, 0, 1, 0, \dots))$. In this case, in order to get explicit examples of the associated b_λ , it is quite useful to have the explicit expression for the associated pre-orbits.

a) The expression of the preimages using $(0, 1, 0, 1, \dots)$. These are $\frac{1}{2}, \frac{1}{4}, \frac{5}{8}, \frac{5}{16}, \dots$. We say that $\frac{1}{2}$ is the 0 level, $\frac{1}{4}$ is the 1 level, $\frac{5}{8}$ is the 2 level, and so on. One can show that, if m is even level, then $\frac{2^{m+2}-1}{3 \cdot 2^{m+1}}$. If m is in odd level the value it is the last one divided by 2.

b) The expression of the preimages using $(1, 0, 1, 0, \dots)$. These are $\frac{1}{2}, \frac{3}{4}, \frac{3}{8}, \frac{11}{16}, \dots$. We say $\frac{1}{2}$ is the 0 level, $\frac{3}{4}$ is the 1 level, $\frac{3}{8}$ is the 2 level,

and so on. One can show that, if m is in odd level, then $\frac{2^{m+2}+1}{3 \cdot 2^{m+1}}$. If m is in even level the value it is the next one multiplied by 2.

7.2. A special quadratic case. As an example let us consider $A(x) = -(x - 1/2)^2 = -1/4 + x - x^2$, then in this case $c_1 = 1$ and $c_2 = -1$

$$\frac{\partial S}{\partial x}(x, a) = \left(\frac{1}{2-\lambda} - \frac{2}{4-\lambda}x \right) - \frac{2}{4-\lambda}Z(a),$$

in particular

$$S(x, a) = S(0, a) + \left(\frac{1}{2-\lambda}x - \frac{1}{4-\lambda}x^2 \right) - \frac{2x}{4-\lambda}Z(a).$$

Thus,

$$\Delta(x, a, b) = S(x, a) - S(x, b) = \Delta(0, a, b) - \frac{2x}{4-\lambda}(Z(a) - Z(b))$$

$$\Delta'(x, a, b) = S'(x, a) - S'(x, b) = -\frac{2}{4-\lambda}(Z(a) - Z(b)).$$

This proves that $A(x) = -(x - 1/2)^2 = -1/4 + x - x^2$ is twist. Indeed, if $a > b$ then $Z(a) > Z(b)$ and so $\Delta'(x, a, b) < 0$. Note that when $\lambda \rightarrow 1$ the angles remain bounded away from zero.

7.3. Crossing points for quadratic potentials. For the case $A(x) = -(x - 1/2)^2$ we can compute explicitly the crossing points $x_{ab} = x$ or equivalently $\Delta(x, a, b) = 0$, that is,

$$x_{ab} = \frac{4-\lambda}{2} \frac{\Delta(0, a, b)}{Z(a) - Z(b)}.$$

7.4. The explicit λ -calibrated subaction for $A(x) = -(x - 1/2)^2$. Remember that $Z(a) = \sum_{k=0}^{\infty} \left(\frac{\lambda}{2}\right)^k a_k$. Note that $Z((01)^\infty) = 0 + \frac{\lambda}{2} + 0 + \left(\frac{\lambda}{2}\right)^3 + 0 + \dots = \frac{\lambda}{2} \frac{4}{4-\lambda^2}$. Moreover, $Z((10)^\infty) = 1 + 0 + \left(\frac{\lambda}{2}\right)^2 + 0 + \left(\frac{\lambda}{2}\right)^4 + 0 + \dots = \frac{4}{4-\lambda^2}$. Note that

$$\begin{aligned} S(x, (01)^\infty) &= S(0, (01)^\infty) + \left(\frac{1}{2-\lambda}x - \frac{1}{4-\lambda}x^2 \right) - \frac{2x}{4-\lambda}Z((01)^\infty) = \\ &S(0, (01)^\infty) + \left(\frac{1}{2-\lambda}x - \frac{1}{4-\lambda}x^2 \right) - \frac{2x}{4-\lambda} \frac{\lambda}{2} \frac{4}{4-\lambda^2} = \\ &S(0, (01)^\infty) + \left(\frac{1}{2-\lambda}x - \frac{1}{4-\lambda}x^2 \right) - \frac{4\lambda x}{(4-\lambda)(4-\lambda^2)} = \\ &S(0, (01)^\infty) + \frac{(8-2\lambda-\lambda^2)x}{(4-\lambda)(4-\lambda^2)} - \frac{1}{4-\lambda}x^2, \end{aligned}$$

and

$$\begin{aligned}
S(x, (10)^\infty) &= S(0, (10)^\infty) + \left(\frac{1}{2-\lambda}x - \frac{1}{4-\lambda}x^2 \right) - \frac{2x}{4-\lambda}Z((10)^\infty) = \\
&S(0, (10)^\infty) + \left(\frac{1}{2-\lambda}x - \frac{1}{4-\lambda}x^2 \right) - \frac{2x}{4-\lambda} \frac{4}{4-\lambda^2} = \\
&S(0, (10)^\infty) + \left(\frac{1}{2-\lambda}x - \frac{1}{4-\lambda}x^2 \right) - \frac{8x}{(4-\lambda)(4-\lambda^2)} = \\
&S(0, (10)^\infty) + \frac{(2\lambda - \lambda^2)x}{(4-\lambda)(4-\lambda^2)} - \frac{1}{4-\lambda}x^2.
\end{aligned}$$

The value $S(0, (10)^\infty)$ will be explicitly obtained in the next proposition.

Observe that $S(1, (01)^\infty) = S(0, (01)^\infty) + \frac{(4-2\lambda)}{(4-\lambda)(4-\lambda^2)}$, and $S(1, (10)^\infty) = S(0, (10)^\infty) + \frac{(2\lambda-4)}{(4-\lambda)(4-\lambda^2)}$. By symmetry (see next proposition) we have that $S(1/2, (10)^\infty) = S(1/2, (01)^\infty)$, and therefore

$$\begin{aligned}
S(1/2, (01)^\infty) &= S(0, (01)^\infty) + \frac{6+\lambda}{4(4-\lambda)(2+\lambda)} = \\
(8) \quad S(1/2, (10)^\infty) &= S(0, (10)^\infty) - \frac{2}{4(4-\lambda)(2+\lambda)}.
\end{aligned}$$

In this way

$$S(0, (10)^\infty) = S(0, (01)^\infty) + \frac{6+\lambda+2}{4(4-\lambda)(2+\lambda)}.$$

Example 32. Here we consider $\lambda = 0.51$ and a periodic and continuous standard twist potential on the circle

$$A(x) = -(x - 0.5)^2$$

that has the maximizing measure in a period two orbit, the superior envelope has two differentiable pieces since the unique turning point $u = 0.5$ pre-periodic. In the figure above, the dots are the iteration of F , the curves are $S(x, 10101\dots)$ and $S(x, 01010\dots)$. The curve dislocated is the graph of $b(x)$ computationally obtained as the superior envelope. The formal proof is given in the next.

Proposition 33. Denote by $b : S^1 \rightarrow \mathbb{R}$ the function such that for $0 \leq x \leq 1/2$, we have $b(x) = S(x, (10)^\infty)$, and for $1/2 \leq x \leq 1$, we have $b(x) = S(x, (01)^\infty)$. Then, b is a λ -calibrated subaction for $A(x) = -(x - 1/2)^2$, that is, for any $x \in S^1$, $b(x) = \max_i \{ \lambda b(\tau_i x) + A(\tau_i x) \} =$

$$(9) \quad \max \{ \lambda b(x/2) + A(x/2), \lambda b(x/2 + 1/2) + A(x/2 + 1/2) \}.$$

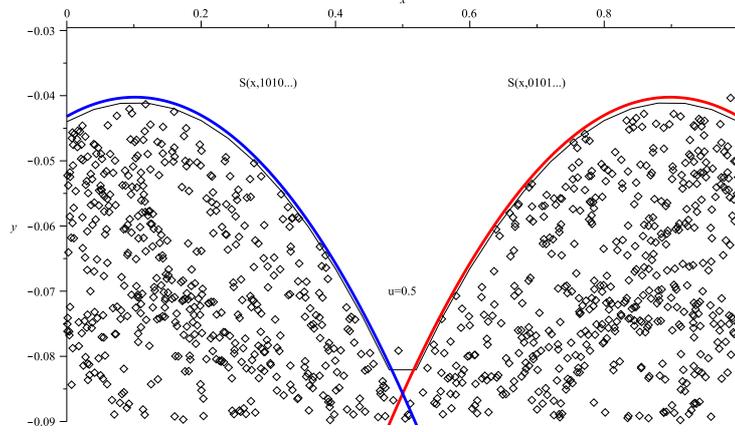

FIGURE 14

Moreover, $b(0) = \frac{2\lambda}{4(4-\lambda)(2+\lambda)(\lambda-1)}$ and this provides the explicit expression of b .

Proof. Note that for a given x we have

$$\begin{aligned}
\lambda b(x/2) + A(x/2) &= \lambda S(x/2, (10)^\infty) + (-1/4 + x/2 - x^2/4) = \\
\lambda [S(0, (10)^\infty) + \frac{(2\lambda - \lambda^2)x}{2(4-\lambda)(4-\lambda^2)} - \frac{1}{4(4-\lambda)}x^2] + (-1/4 + x/2 - x^2/4) &= \\
\lambda S(0, (10)^\infty) + \lambda \frac{(2\lambda - \lambda^2)x}{2(4-\lambda)(4-\lambda^2)} - \lambda \frac{1}{4(4-\lambda)}x^2 + (-1/4 + x/2 - x^2/4) &= \\
S(0, (01)^\infty) - A(0) + \lambda \frac{(2\lambda - \lambda^2)x}{2(4-\lambda)(4-\lambda^2)} - & \\
\lambda \frac{1}{4(4-\lambda)}x^2 + (-1/4 + x/2 - x^2/4) &= \\
S(0, (01)^\infty) + \lambda \frac{(2\lambda - \lambda^2)x}{2(4-\lambda)(4-\lambda^2)} - \lambda \frac{1}{4(4-\lambda)}x^2 + x/2 - x^2/4 &= \\
S(0, (01)^\infty) + \frac{(-\lambda^2 - 2\lambda + 8)x}{(4-\lambda)(4-\lambda^2)} - \frac{x^2}{(4-\lambda)} &= S(x, (01)^\infty),
\end{aligned}$$

As A is symmetric we claim that $S(x, (10)^\infty) = S((1-x), (01)^\infty)$.

Indeed,

$$\begin{aligned}
S(x, (10)^\infty) &= \sum_{k=0}^{\infty} \lambda^k A(\tau_{a_k} \circ \tau_{a_{k-1}} \circ \dots \circ \tau_{a_0}(x)) = \\
&A(\tau_1(x)) + \lambda A(\tau_0 \circ \tau_1(x)) + \lambda^2 A(\tau_1 \circ \tau_0 \circ \tau_1(x)) + \dots = \\
&A((x+1)/2) + \lambda A(\frac{1}{2}((x+1)/2)) + \lambda^2 A(\tau_1(\frac{1}{2}((x+1)/2))) + \dots =
\end{aligned}$$

$$\begin{aligned}
& A((x+1)/2) + \lambda A\left(\frac{1}{2} + (x/4 - 1/4)\right) + \lambda^2 A\left(\tau_1\left(\frac{1}{2}\left(\frac{(x+1)}{2}\right)\right)\right) + \dots = \\
& A(1/2 - x) + \lambda A\left(\frac{1}{2} - (x/4 - 1/4)\right) + \lambda^2 A\left(\frac{\left(\frac{1}{2}\left(\frac{(x+1)}{2}\right)\right) + 1}{2}\right) + \dots = \\
& A(\tau_0(1-x)) + \lambda A(\tau_1 \circ \tau_0(1-x)) + \lambda^2 A(\tau_0 \circ \tau_1 \circ \tau_0(1-x)) + \dots = \\
(10) \quad & S((1-x), (01)^\infty).
\end{aligned}$$

Therefore, $b(x) = b(1-x)$. Moreover, $S(1/2, (10)^\infty) = S(1/2, (01)^\infty)$. Using this symmetry we get $\lambda b(x/2+1/2) + A(x/2+1/2) = S(x, (10)^\infty)$ from (10). From the above it follows (9). Note that from (8) we have

$$\begin{aligned}
b(0) &= \max\{\lambda b(0) + A(0), \lambda b(1/2) + A(1/2)\} = \\
& \max\{\lambda b(0) - 1/4, \lambda b(1/2)\} = \\
& \max\{\lambda S(0, (10)^\infty) - 1/4, \lambda S(1/2, (10)^\infty)\} = \\
& \max\{\lambda S(0, (10)^\infty) - 1/4, \lambda S(0, (10)^\infty) - \frac{2\lambda}{4(4-\lambda)(2+\lambda)}\} = \\
& \max\{\lambda b(0) - 1/4, \lambda b(0) - \frac{2\lambda}{4(4-\lambda)(2+\lambda)}\} = \lambda b(0) - \frac{2\lambda}{4(4-\lambda)(2+\lambda)}.
\end{aligned}$$

In this way $S(0, (10)^\infty) = b(0) = \frac{2\lambda}{4(4-\lambda)(2+\lambda)(\lambda-1)}$. \square

8. WORKED EXAMPLES AND COMPUTER SIMULATIONS

In the simulations we consider the function $S : (S^1, \{1, 2, \dots, d\}^{\mathbb{N}}) \rightarrow \mathbb{R}$ given by $S(x, a) = \sum_{k=0}^{\infty} \lambda^k A((\tau_{a_k} \circ \tau_{a_{k-1}} \circ \dots \circ \tau_{a_0})(x))$, and, $a = (a_0, a_1, a_2, \dots)$. The dynamics is defined by the inverse branches of $2x \bmod 1$, that is $\tau_0 = 0.5x$, $\tau_1 = 0.5x + 0.5$, $A(x)$ is a potential and $\lambda = 0.51$. We will built examples where $a = (a_0, a_1, a_2, \dots)$ is truncated in a_7 , and the dots represents the iteration of typical orbits by $F(x, s) = (T(x), \lambda s + A(x))$, $(x, s) \in S^1 \times \mathbb{R}$ producing a picture of the superior envelope of the attractor.

Example 34. *Here we consider a periodic and continuous potential on the circle $A(x) = -(x - 0.5)^2 + \varepsilon\psi(x)$ - drift for $\varepsilon = 0.05$, drift $= 0.2$ and $\psi(x) = (x - x^2)(1 + 3x + 9/2x^2 + 9/2x^3 + \frac{27}{8}x^4 + \frac{81}{40}x^5)$. Since $-(x - 0.5)^2$ is twist and has the maximizing measure in a period two orbits the same is true for A , but in this case, the superior envelope has three differentiable pieces and turning points $u = 0.21\dots$ and $v = 0.60\dots$. In the figure above, the dots are the iteration of F , the curves are*

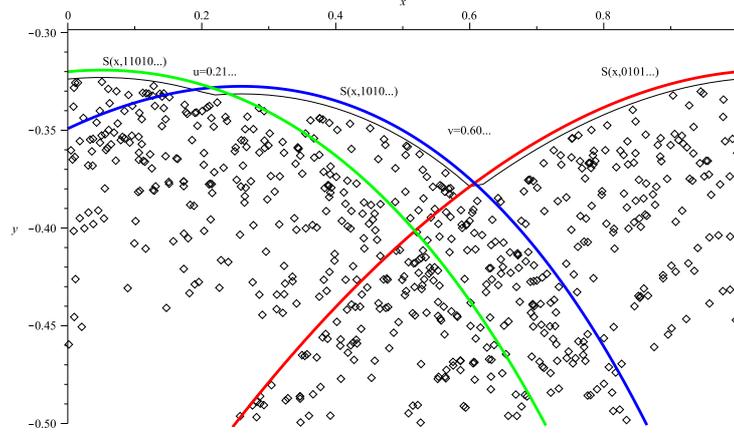

FIGURE 15

$S(x, 11010\dots)$, $S(x, 10101\dots)$ and $S(x, 01010\dots)$. The curve dislocated is the graph of $b(x)$ computationally obtained as the superior envelope:

$$b(x) := \begin{cases} S(x, 110101\dots) & , \quad 0 < x \leq u \\ S(x, 101010\dots) & , \quad u < x \leq v \\ S(x, 010101\dots) & , \quad v < x \leq 1 \end{cases} .$$

Example 35. Here we consider a periodic and continuous potential on the circle

$$A(x) = \begin{cases} 6x - 3, & x < 1/2 \\ -6x + 3, & x \geq 1/2 \end{cases}$$

that is not twist but in this case, the superior envelope has two differentiable pieces since the unique turning point is pre-periodic according to Corollary 24. In the figure above, the dots are obtained by the iteration of F in an initial point and the curves are the graphs of $S(x, 10101\dots)$ and $S(x, 01010\dots)$. The curve slightly dislocated is the graph of $b(x)$ computationally obtained as the superior envelope.

Example 36. Here we consider a periodic and differentiable potential on the circle

$$A(x) = -1/2 - 1/2 \cos(2\pi x)$$

that is not necessarily twist but in this case, the superior envelope has two differentiable pieces since the unique turning point is pre-periodic according to Corollary 24. In the figure above, the dots are the iteration of F in an initial point and the curves are defined by $S(x, 10101\dots)$ and $S(x, 01010\dots)$. The curve slightly dislocated is the graph of $b(x)$ computationally obtained as the superior envelope.

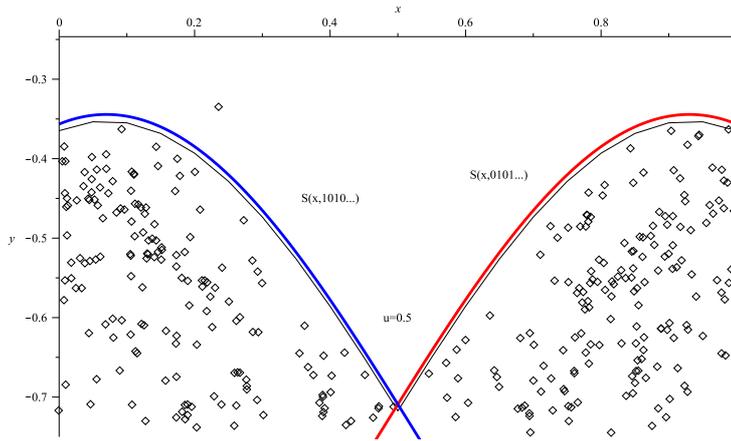

FIGURE 17

9. ERGODIC TRANSPORT

In this section A is assumed to be just Lipschitz. Following the notation of section 2 we point out that: given $x = x_0$, there exists a sequence $x_k \in S^1$, $k \in \mathbb{N}$, such that $b(x_{k-1}) - \lambda b(\tau_{i_k}(x_k)) - A(\tau_{i_k}(x_k)) = 0$. One can consider the probability $m_n = \sum_{j=0}^{n-1} \frac{1}{n} \delta_{\sigma^j(a)}$, where σ is the shift, and, $a = a(x_0)$ is optimal for x_0 . We define the probability μ_λ^* in $\{1, 2, \dots, d\}^{\mathbb{N}}$, as any weak limit of a convergent subsequence m_{n_k} , $k \rightarrow \infty$ (which will be σ invariant).

Definition 37. We call μ_λ^* a λ -dual probability for A .

Note that from Proposition 3 if z is in the support of the λ -maximizing probability μ_λ , then $a(z)$ can be taken as periodic orbit for σ . In this case following the above reasoning we can produce a certain μ_λ^* which has support in a periodic orbit.

Consider a fixed $\bar{x} \in S^1$. Remember that we denote

$$A^*(a) = [\lambda S(\bar{x}, \sigma(a)) - S(\bar{x}, a)],$$

and in this way we get that for any (x, a)

$$A^*(a) = A(\tau_{a_0}(x)) + [\lambda W(\tau_{a_0}(x), \sigma(a)) - W(x, a)],$$

where $W(x, a) = S(x, a) - S(\bar{x}, a)$. We called such W the λ -involution kernel for A . We called A^* is the λ -dual potential of A . The main strategy is to get results for A from properties of A^* . This is similar to the approach via primal and dual problems in Linear Programming. Note that W depends on the \bar{x} we choose. Therefore, $A^* = A_{\bar{x}}^*$ depends of the \bar{x} . If we consider another base point x_1 instead \bar{x} , in order to get a different $W_1(x, a) = S(x, a) - S(x_1, a)$, then one can show that the corresponding A_1^* (to A and W_1) satisfies $A_1^* = A^* + \lambda(g \circ \sigma) - g$, for some continuous g . Note that $W - W_1$ just depends on a .

For the dual problem it will be necessary to consider the following problem: finding a function $b^* = b_\lambda^*$ which satisfies for all $a \in \Sigma$

$$\lambda b^*(a) = \max_{\sigma(c)=a} \{b^*(c) + A^*(c)\}.$$

In fact one can do more, it is possible to find a continuous function b^* that solves $\lambda b^*(\sigma(c)) = b^*(c) + A^*(c)$, $\forall c \in \Sigma$.

Just take, as in [3], $b^*(c) = -\sum_{j=0}^{\infty} \lambda^j A^*(\sigma^j(c)) =$

$$-\sum_{j=0}^{\infty} \lambda^j [\lambda S(\bar{x}, \sigma^{j+1}(c)) - S(\bar{x}, \sigma^j(c))] = -S(\bar{x}, c).$$

In this case the corresponding rate function in the dual problem $R^*(c) = \lambda b^*(\sigma(c)) - b^*(c) - A^*(c)$ is constant equal zero. This situation is quite different from the analogous dual problem in [30].

Definition 38. We call b_λ^* the dual λ -calibrated subaction.

We assume, without lost of generality, that $A > 0$. Then, $b > 0$. It is natural to consider the sum $\sum R^*(\sigma^n)(z)$ in the dual problem (see [4], [30] and [12]) but now this sum is zero. The role of the dual subactions V and V^* of [30] are now played by b and b^* , which are, respectively, the λ -calibrated subactions for A and A^* . Note that for all (x, a)

$$(b^* + b - W)(x, a) = -S(\bar{x}, a) + b(x) + S(\bar{x}, a) - S(x, a) =$$

$$b(x) - S(x, a) \geq 0.$$

If a is a realizer for x , then $(b^* + b - W)(x, a) = 0$. Given A (and, a certain choice of A^* and W) the next result claims that the dual of R is R^* (which is constant equal zero), and the corresponding involution kernel is $(b^* + b - W)$.

Proposition 39.

$$R(\tau_w x) = (b^* + b - W)(x, w) - \lambda(b^* + b - W)(\tau_w x, \sigma(w)).$$

Proof. We know that $\lambda b^*(\sigma(w)) - b^*(w) = A^*(w)$, and, now using $x = T(\tau_w x)$, we get

$$\begin{aligned} b(x) - \lambda b(\tau_w x) &= b(T(\tau_w x)) - \lambda b(\tau_w x) = \\ &= -A(\tau_w x) + A(\tau_w x) = R(\tau_w x) + A(\tau_w x). \end{aligned}$$

Substituting the above in the previous equation we get

$$\begin{aligned} &(b^* + b - W)(x, w) - \lambda(b^* + b - W)(\tau_w(x), \sigma(w)) = \\ &[b^*(w) - \lambda b^*(\sigma(w))] + [b(x) - \lambda b(\tau_w x)] - W(x, w) + \lambda W(\tau_w x, \sigma(w)) = \\ &-A^*(w) + R(\tau_w(x)) + A(\tau_w(x)) + \lambda W(\tau_w(x), \sigma(w)) - W(x, w) = R(\tau_w(x)), \end{aligned}$$

because $A^*(w) = A(\tau_w x) + \lambda W(\tau_w x, \sigma(w)) - W(x, w)$. So the claim follows. \square

We present now a brief outline of Transport Theory (see [37] [38] as a general reference).

Definition 40. We denote by $\mathcal{K}(\mu, \mu^*)$ the set of probabilities $\hat{\eta}(x, w)$ on $\hat{\Sigma} = S^1 \times \Sigma$, such that $\pi_x^*(\hat{\eta}) = \mu$, and $\pi_w^*(\hat{\eta}) = \mu^*$. Each element in $\mathcal{K}(\mu, \mu^*)$ is called a plan.

In Transport Theory one is interested in plans which minimize the integral a given lower semi-continuous cost $c : \Sigma \rightarrow \mathbb{R}$. The Classical Transport Theory is not a Dynamical Theory. It is necessary to consider a dynamically defined cost in order to be able to get some results such that the optimal plan is invariant for some dynamics. We are going to consider below the cost function $c(x, w) = -W(x, w) = -W_\lambda(x, w)$ where $W(x, w)$ is a λ -involution kernel of the Lipschitz potential A . The Kantorovich Transport Problem: consider the minimization problem

$$C(\mu, \mu^*) = \inf_{\hat{\eta} \in \mathcal{K}(\mu, \mu^*)} \int \int -W(x, w) d\hat{\eta}.$$

Definition 41. A probability $\hat{\eta}$ on $\hat{\Sigma}$ which attains such infimum is called an optimal transport probability, or, an optimal plan, for $c = -W$.

It is natural to consider the bijective transformation \mathbb{T} which acts on $\hat{\Sigma} = S^1 \times \Sigma$ in such way that $\mathbb{T}^{-1}(x, w) = (\tau_w x, \sigma(w))$. We will show later that for μ_λ and μ_λ^* there exists a \mathbb{T} -invariant probability $\hat{\mu}_{min}$ which attains the optimal transport cost. Dynamically defined costs can determine optimal plans which have dynamical properties.

Definition 42. *A pair of continuous functions $f(x)$ and $f^\#(w)$ will be called c -admissible (or, just admissible for short) if*

$$f^\#(w) = \min_{x \in S^1} \{-f(x) + c(x, w)\}.$$

We denote by \mathcal{F} the set of admissible pairs. The Kantorovich dual Problem: given the cost $c(x, w)$ consider the maximization problem

$$D(\mu, \mu^*) = \max_{(f, f^\#) \in \mathcal{F}} \left(\int f d\mu + \int f^\# d\mu^* \right).$$

In this problem one is interested in any pair (when exists) $(f, f^\#) \in \mathcal{F}$ which realizes the maximum in the right side of the above expression.

Definition 43. *A pair of admissible $(f, f^\#) \in \mathcal{F}$ which attains the maximum value will be called an optimal Kantorovich pair.*

Under quite general conditions [37] (which are satisfied here) $D(\mu, \mu^*) = C(\mu, \mu^*)$. We denote

$$\Gamma = \Gamma_b = \{(x, w) \in S^1 \times \Sigma \mid b(x) = (-b^* + W)(x, w)\}.$$

A classical result in Transport Theory [37]: if $\hat{\eta}$ is a probability in $\mathcal{K}(\mu, \mu^*)$, $(f, f^\#)$ is an admissible pair, and the support of $\hat{\eta}$ is contained in the set $\{(x, w) \in \hat{\Sigma} \mid \text{such that } (f(x) + f^\#(w)) = c(x, w)\}$, then, $\hat{\eta}$ in an optimal plan for c and $(f, f^\#)$ is an optimal pair in \mathcal{F} .

This is the so called slackness condition of Linear Programming (see [38] Remark 5.13 page 59). This results allows one to get in some cases the solution of the primal problem (which is looking for optimal plans) via de dual problem (which is looking for optimal pairs of functions). If you have a good guess that a certain $\hat{\eta}$ is the optimal plan you can try to find an admissible pair satisfying the above condition on the support of the plan. If you succeeded then you show that the plan $\hat{\eta}$ is indeed the solution of the transport problem. This is the power of the dual problem approach.

We will show that for the problem $D(\mu_\lambda, \mu_\lambda^*)$ the functions $-b$ and $-b^*$ define an optimal Kantorovich pair. From this fact becomes clear the importance of the set Γ .

Our main result in this section is:

Theorem 44. *For the probabilities $\mu_\lambda, \mu_\lambda^*$ and the cost $-W$, the associated transport problem is such that the functions $-b$ and $-b^*$ define an optimal Kantorovich pair, and, the optimal plan is invariant by \mathbb{T} .*

Proof. We claim first that $-b$ and $-b^*$ are $-W$ -admissible. Indeed, $p(x, w) := (b^* + b - W)(x, w) \geq 0$. Moreover, for each x there exists a w which is a realizer and then $p(x, w) = 0$. Therefore, for each x we have that

$$(11) \quad b(x) = \max_{w \in \Sigma} \{-b^*(w) + W(x, w)\} = \max_{w \in \Sigma} S(x, w).$$

□

For each x we denote $w_x \in \Sigma$ the realizer for the above equation. We can say that b is the W transform of $-b^*$ [37] and [38]. Note that

$$\Gamma = \{(x, w) \in S^1 \times \Sigma \mid p(x, w) = 0\}.$$

We will show that the infimum of the cost $-W$, denoted $c(A, \lambda)$, is equal to $\int -b^* d\mu_\lambda^* + \int -b d\mu_\lambda$.

The next proposition is similar to a result on [30]. Remember that $R = -(A - b \circ T + \lambda b) \geq 0$ is called the rate function.

Proposition 45. (Fundamental relation) *For any (x, w)*

$$(12) \quad R(\tau_w x) = p(x, w) - \lambda p(\tau_w x, \sigma(w))$$

Moreover, if $\mathbb{T}^{-1}(x, w) = (\tau_w x, \sigma(w))$, then

- a) $p - \lambda p \circ \mathbb{T}^{-1}(x, w) = R(\tau_w x) \geq 0$;
- b) Γ is invariant by the action of \mathbb{T}^{-1} ;
- c) if $a = (i_0, i_1, i_2, \dots)$ is optimal for x , then $\sigma^n(a)$ is optimal for $(\tau_{i_{n-1}} \circ \dots \circ \tau_{i_1} \circ \tau_{i_0})(x)$.

Proof. The first claim a) is a trivial consequence of the definition of \mathbb{T}^{-1} . The second one it is a consequence of: $p \geq 0$, and

$$p - \lambda (p \circ \mathbb{T}^{-1})(x, w) \geq 0 \Rightarrow p(x, w) \geq \lambda (p \circ \mathbb{T}^{-1})(x, w).$$

From the above we get that in the case (x, w) is optimal, then, $\mathbb{T}^{-1}(x, w)$ is also optimal. Indeed, we have that

$$p(x, w) = 0 \rightarrow p(\tau_w(x), \sigma(w)) = 0.$$

Item c) follows by induction. □

In this way \mathbb{T}^{-n} spread optimal pairs. This is a nice property that has no counterpart in the Classical Transport Theory.

Take now $(z_0, w_0) \in \Gamma_V$ and, for each n , $\hat{\mu}_n = \frac{1}{n} \sum_{j=0}^{n-1} \delta_{\mathbb{T}^{-j}(z_0, w_0)}$. Note that $\mathbb{T}^{-j}(z_0, w_0)$ is optimal. The closure of the set $\{\mathbb{T}^{-j}(z_0, w_0), j \in \mathbb{N}\}$ is contained in the support of the optimal transport plan.

Proposition 46. *We claim that any weak limit of convergent subsequence $\hat{\mu}_{n_k}$, $k \rightarrow \infty$, will define a probability $\hat{\mu}$ which is optimal for the transport problem for $-W$ and its marginals. In this way we will show the existence of a \mathbb{T} -invariant probability on $S^1 \times \Sigma$ which is optimal for the associated transport problem.*

Proof. Indeed, we considered before a certain z_0 , its realizer w_0 , and then a convergent subsequence μ_{n_k} (notation of last section), $n_k \rightarrow \infty$, in order to get μ_λ . If we consider above the corresponding subsequence $\mathbb{T}^{-n_k}(z_0, w_0)$ we get that the projection of $\hat{\mu}$ on the S^1 coordinate is μ_λ .

In an analogous way, we consider as before a certain z_0 , its realizer w_0 , and then a convergent subsequence m_k to define μ_λ^* . If we consider above a subsequence m_k of the previous sequence n_k (last paragraph) we get that the projection of $\hat{\mu}$ on the Σ coordinate is μ_λ^* . As $p(x, w) = (b^* + b - W)(x, w)$ and p is zero on the orbit $\mathbb{T}^{-n_k}(z_0, w_0)$ we get that g is also zero in the support of any associated weak convergent subsequence. Then any probability $\hat{\mu}$ obtained in this way is such that projects respectively on μ_λ and μ_λ^* , and, moreover, satisfies

$$\int -W d\hat{\mu} = \int (-b^*) d\mu^* + \int (-b) d\mu_\lambda.$$

Therefore, $C(\mu, \mu^*) = \int (-b^*) d\mu^* + \int (-b) d\mu_\lambda$. \square

We point out that for the purpose of proving the conjecture the next proposition is the key result. It is just a trivial consequence of Theorem 44 and expression (11).

Proposition 47. *Suppose that A is Lipschitz, the maximizing probability μ_λ has support in a unique periodic orbit of period k and μ_λ^* is a dual λ -maximizer with support on the dual periodic orbit of period k for σ , then*

$$b(x) = \max_{w \in \Sigma} \{-b^*(w) + W(x, w)\} = -b^*(a) + W(x, a) =$$

$$S(x, a) = \max_{w \in \Sigma} S(x, w),$$

where $a = a(x)$ is the periodic realizer of x . In this case a is in the support of μ_λ^* . Moreover, the procedure: given $(z_0, a(z_0)) \in \Gamma_V$ take $\hat{\nu}$

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} \delta_{\mathbb{T}^{-j}(z_0, a(z_0))} = \hat{\nu},$$

is such that $\hat{\nu}$ is optimal and has support on a periodic orbit for \mathbb{T} . In the support of $\hat{\nu}$ we have $b(x) + b^*(a(x)) = W(x, a(x))$.

Proposition 48. *Suppose W satisfies a twist condition. Denote by $\mathfrak{w} : S^1 \rightarrow \Sigma$ the function such that for a given x we have that $\mathfrak{w}(x)$ is a choice of the eventual possible w_x as defined above. Then, \mathfrak{w} is monotonous non-decreasing (using the lexicographic order in Σ)*

The proof of this proposition is the same as the one in Proposition 6.2 in [30] or Proposition 2.1 in [12]. In [28] other kinds of results in Ergodic Transport Theory are considered.

Consider $0 < \lambda < 1$, and the map $G(w, s) = (\sigma(w), \lambda s + A^*(w))$, where $G : \{1, 2, \dots, d\}^{\mathbb{N}} \times \mathbb{R} \rightarrow \{1, 2, \dots, d\}^{\mathbb{N}} \times \mathbb{R}$, and $A^* : \{1, 2, \dots, d\}^{\mathbb{N}} \rightarrow \mathbb{R}$ is the dual potential.

The dynamics of attractor for F has associated to it a dual repellor naturally defined by G acting on $\{1, 2, \dots, d\}^{\mathbb{N}} \times \mathbb{R}$. The boundary of the repellor set is the graph of $b^* : \{1, 2, \dots, d\}^{\mathbb{N}} \rightarrow \mathbb{R}$ which is the λ -dual calibrated subaction.
